# Rocky Enterprise Linux 9.2 Manual Pages on command 'backtrace_symbols.3'

**$ man backtrace_symbols.3**

NAME

   backtrace,  backtrace_symbols,  backtrace_symbols_fd - support for application self-debug?

   ging

SYNOPSIS

   #include <execinfo.h>

   int backtrace(void **buffer, int size);

   char **backtrace_symbols(void *const *buffer, int size);

   void backtrace_symbols_fd(void *const *buffer, int size, int fd);

DESCRIPTION

   backtrace() returns a backtrace for the calling program, in the array pointed to  by  buf?

   fer.   A backtrace is the series of currently active function calls for the program.  Each

   item in the array pointed to by buffer is of type void *, and is the return  address  from

   the  corresponding  stack  frame.   The  size argument specifies the maximum number of ad?

   dresses that can be stored in buffer.  If the backtrace is larger than size, then the  ad?

   dresses  corresponding  to the size most recent function calls are returned; to obtain the

   complete backtrace, make sure that buffer and size are large enough.

   Given the set of addresses returned by backtrace() in buffer,  backtrace_symbols()  trans?

   lates  the  addresses  into  an array of strings that describe the addresses symbolically.

   The size argument specifies the number of addresses in buffer.  The  symbolic  representa?

   tion of each address consists of the function name (if this can be determined), a hexadec?

   imal offset into the function, and the actual return address (in  hexadecimal).   The  ad?

   dress of the array of string pointers is returned as the function result of backtrace_sym?

bols().  This array is malloc(3)ed by  backtrace_symbols(),  and  must  be  freed  by  the
caller.  (The  strings  pointed  to  by  the array of pointers need not and should not be
freed.)

backtrace_symbols_fd() takes the same buffer and size  arguments  as  backtrace_symbols(),
but instead of returning an array of strings to the caller, it writes the strings, one per
line, to the file descriptor fd.  backtrace_symbols_fd() does not call malloc(3),  and  so
can be employed in situations where the latter function might fail, but see NOTES.

## RETURN VALUE

backtrace()  returns the number of addresses returned in buffer, which is not greater than
size.  If the return value is less than size, then the full backtrace was stored; if it is
equal  to size, then it may have been truncated, in which case the addresses of the oldest
stack frames are not returned.

On success, backtrace_symbols() returns a pointer to the array malloc(3)ed by the call; on
error, NULL is returned.

## VERSIONS

backtrace(),  backtrace_symbols(),  and backtrace_symbols_fd() are provided in glibc since
version 2.1.

## ATTRIBUTES

For an explanation of the terms used in this section, see attributes(7).

```

?backtrace(),        ? Thread safety ? MT-Safe ?
?backtrace_symbols(),   ?          ?       ?
?backtrace_symbols_fd() ?          ?      ?
?????????????????????????????????????????????????????
```

## CONFORMING TO

These functions are GNU extensions.

## NOTES

These functions make some assumptions about how a function's return address is  stored  on
the stack.  Note the following:

*  Omission of the frame pointers (as implied by any of gcc(1)'s nonzero optimization lev?
   els) may cause these assumptions to be violated.

* Inlined functions do not have stack frames.

* Tail-call optimization causes one stack frame to replace another.

* backtrace() and backtrace_symbols_fd() don't call malloc() explicitly, but they are part of libgcc, which gets loaded dynamically when first used. Dynamic loading usually triggers a call to malloc(3). If you need certain calls to these two functions to not allocate memory (in signal handlers, for example), you need to make sure libgcc is loaded beforehand.

The symbol names may be unavailable without the use of special linker options. For sys? tems using the GNU linker, it is necessary to use the -rdynamic linker option. Note that names of "static" functions are not exposed, and won't be available in the backtrace.

EXAMPLES

The program below demonstrates the use of backtrace() and backtrace_symbols(). The fol? lowing shell session shows what we might see when running the program:

```
$ cc -rdynamic prog.c -o prog
$ ./prog 3
backtrace() returned 8 addresses
./prog(myfunc3+0x5c) [0x80487f0]
./prog [0x8048871]
./prog(myfunc+0x21) [0x8048894]
./prog(myfunc+0x1a) [0x804888d]
./prog(myfunc+0x1a) [0x804888d]
./prog(main+0x65) [0x80488fb]
/lib/libc.so.6(__libc_start_main+0xdc) [0xb7e38f9c]
./prog [0x8048711]
```

Program source

```
#include <execinfo.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#define BT_BUF_SIZE 100
void
myfunc3(void)
{
```

```c
    int nptrs;
    void *buffer[BT_BUF_SIZE];
    char **strings;

    nptrs = backtrace(buffer, BT_BUF_SIZE);
    printf("backtrace() returned %d addresses\n", nptrs);

    /* The call backtrace_symbols_fd(buffer, nptrs, STDOUT_FILENO)
       would produce similar output to the following: */

    strings = backtrace_symbols(buffer, nptrs);
    if (strings == NULL) {
        perror("backtrace_symbols");
        exit(EXIT_FAILURE);
    }

    for (int j = 0; j < nptrs; j++)
        printf("%s\n", strings[j]);

    free(strings);
}

static void   /* "static" means don't export the symbol... */
myfunc2(void)
{
    myfunc3();
}

void
myfunc(int ncalls)
{
    if (ncalls > 1)
        myfunc(ncalls - 1);
    else
        myfunc2();
}

int
main(int argc, char *argv[])
{
    if (argc != 2) {
```

```
        fprintf(stderr, "%s num-calls\n", argv[0]);

        exit(EXIT_FAILURE);

    }

    myfunc(atoi(argv[1]));

    exit(EXIT_SUCCESS);

}
```
