\$ man dh_pypy.1

DH_PYPY(1)

DH_PYPY(1)

NAME

dh_pypy - calculates PyPy dependencies, adds maintainer scripts to byte compile files, etc.

SYNOPSIS

dh_pypy -p PACKAGE [-V [X.Y][-[A.B]] DIR [-X REGEXPR]

DESCRIPTION

QUICK GUIDE FOR MAINTAINERS

- ? build-depend on pypy and dh-python,
- ? add \${pypy:Depends} to Depends
- ? build module/application using its standard build system,
- ? install files to the standard locations,
- ? add pypy to dh's --with option, or:
- ? call dh_pypy in the binary-* target,

NOTES

dependencies

dh_pypy tries to translate Python dependencies from the requires.txt file to Debian dependencies. In many cases, this works without any additional configuration because dh_pypy comes with a build-in mapping of Python module names to Debian packages that is periodically regenerated from the Debian archive. By default, the version information in the Python dependencies is discarded. If you want dh_pypy to generate more strict dependencies (e.g. to avoid ABI problems), or if the automatic

mapping does not work correctly for your package, you have to provide `dh_pypy` with additional rules for the translation of Python module to Debian package dependencies.

For a package `pypy-foo` that depends on a package `pypy-bar`, there are two files that may provide such rules:

1. If the `pypy-foo` source package ships with a `debian/pypy-overrides` file, this file is used by `dh_pypy` during the build of `pypy-foo`.
2. If the `pypy-bar` source package ships with a `debian/pypy-bar.pydist` file (and uses `dh_pypy`), this file will be included in the binary package as `/usr/share/dh-python/dist/pypy/pypy-bar`. During the build of `pypy-foo`, `dh_pypy` will then find and use the file.

Both files have the same format described in `/usr/share/doc/dh-python/README.PyDist`. If all you want is to generate versioned dependencies (and assuming that the `pypy-bar` package provides the `pybar` Python module), in most cases it will be sufficient to put the line `pybar pypy-bar; PEP386` into either of the above files.

namespace feature

`dh_pypy` parses Egg's `namespace_packages.txt` files (in addition to `--namespace-command-line` argument(s)) and drops empty `__init__.py` files from binary package. `pypycompile` will regenerate them at install time and `pypyclean` will remove them at uninstall time (if they're no longer used in installed packages). It's still a good idea to provide `__init__.py` file in one of binary packages (even if all other packages use this feature).

private dirs

`/usr/share/foo`, `/usr/share/games/foo`, `/usr/lib/foo` and `/usr/lib/games/foo` private directories are scanned for Python files by default (where `foo` is binary package name). If your package ships Python files in some other directory, add another `dh_pypy` call in `debian/rules` with directory name as an argument - you can use different set of options in this call. If you need to change options for a private directory that is checked by default, invoke `dh_pypy` with `--skip-private` option and add another call with a path to this directory and new options.

debug packages

In binary packages which name ends with `-dbg`, all files in `/usr/lib/pypy/dist-packages/` directory that have extensions different than `so` or `h` are removed by default.

Use `--no-dbg-cleaning` option to disable this feature.

overriding supported / default PyPy versions

If you want to override system's list of supported PyPy versions or the default one (f.e. to build a package that includes symlinks for older version of PyPy or compile .py files only for given interpreter version), you can do that via `DEBPYPY_SUPPORTED` and/or `DEBPYPY_DEFAULT` env. variables.

OPTIONS

`--version`

show program's version number and exit

`-h, --help`

show help message and exit

`--no-guessing-deps`

disable guessing dependencies

`--no-dbg-cleaning`

do not remove any files from debug packages

`--no-ext-rename` do not add magic tags nor multiarch tuples to extension file names

`--no-shebang-rewrite`

do not rewrite shebangs

`--skip-private`

don't check private directories

`-v, --verbose`

turn verbose mode on

`-i, --indep`

act on architecture independent packages

`-a, --arch`

act on architecture dependent packages

`-q, --quiet`

be quiet

`-p PACKAGE, --package=PACKAGE`

act on the package named PACKAGE

`-N NO_PACKAGE, --no-package=NO_PACKAGE`

do not act on the specified package

`-X REGEXPR, --exclude=REGEXPR`

exclude items that match given REGEXPR. You may use this option multiple times to build up a list of things to exclude.

`--compile-all`

compile all files from given private directory in `postinst/rtupdate` not just the ones provided by the package (i.e. do not pass the `--package` parameter to `py3compile/py3clean`)

`--accept-upstream-versions`

accept upstream versions while translating Python dependencies into Debian ones

`--depends=DEPENDS`

translate given requirements into Debian dependencies and add them to `$(pypy:Depends)`. Use it for missing items in `requires.txt`

`--depends-sections=SECTIONS`

translate requirements from given sections of `requires.txt` file into Debian dependencies and add them to `$(pypy:Depends)`.

`--recommends=RECOMMENDS`

translate given requirements into Debian dependencies and add them to `$(pypy:Recommends)`

`--recommends-sections=SECTIONS`

translate requirements from given sections of `requires.txt` file into Debian dependencies and add them to `$(pypy:Recommends)`.

`--suggests=SUGGESTS`

translate given requirements into Debian dependencies and add them to `$(pypy:Suggests)`

`--suggests-sections=SECTIONS`

translate requirements from given sections of `requires.txt` file into Debian dependencies and add them to `$(pypy:Suggests)`.

`--requires=FILENAME`

translate requirements from given file(s) into Debian dependencies and add them to `$(pypy:Depends)`

`--shebang=COMMAND`

use given command as shebang in scripts

`--ignore-shebangs`

do not translate shebangs into Debian dependencies
