LOOP(4)

Linux Programmer's Manual

LOOP(4)

NAME

loop, loop-control - loop devices

#### SYNOPSIS

#include <linux/loop.h>

#### DESCRIPTION

The loop device is a block device that maps its data blocks not to a physical device such

as a hard disk or optical disk drive, but to the blocks of a regular file in a filesystem

or to another block device. This can be useful for example to provide a block device for

a filesystem image stored in a file, so that it can be mounted with the mount(8) command.

You could do

\$ dd if=/dev/zero of=file.img bs=1MiB count=10

\$ sudo losetup /dev/loop4 file.img

\$ sudo mkfs -t ext4 /dev/loop4

\$ sudo mkdir /myloopdev

\$ sudo mount /dev/loop4 /myloopdev

See losetup(8) for another example.

A transfer function can be specified for each loop device for encryption and decryption purposes.

The following ioctl(2) operations are provided by the loop block device:

# LOOP\_SET\_FD

Associate the loop device with the open file whose file descriptor is passed as the

(third) ioctl(2) argument.

# LOOP\_CLR\_FD

Disassociate the loop device from any file descriptor.

# LOOP\_SET\_STATUS

Set the status of the loop device using the (third) ioctl(2) argument. This argu? ment is a pointer to a loop\_info structure, defined in <linux/loop.h> as:

struct loop\_info {

lo\_number; /\* ioctl r/o \*/ int lo\_device; /\* ioctl r/o \*/ dev\_t /\* ioctl r/o \*/ unsigned long lo inode; dev t lo rdevice; /\* ioctl r/o \*/ int lo\_offset; int lo\_encrypt\_type; lo\_encrypt\_key\_size; /\* ioctl w/o \*/ int int lo\_flags; /\* ioctl r/w (r/o before Linux 2.6.25) \*/ char lo\_name[LO\_NAME\_SIZE]; unsigned char lo\_encrypt\_key[LO\_KEY\_SIZE]; /\* ioctl w/o \*/

unsigned long lo\_init[2];

char reserved[4];

```
};
```

The encryption type (lo\_encrypt\_type) should be one of LO\_CRYPT\_NONE, LO\_CRYPT\_XOR,

```
LO_CRYPT_DES, LO_CRYPT_FISH2, LO_CRYPT_BLOW, LO_CRYPT_CAST128, LO_CRYPT_IDEA,
```

LO\_CRYPT\_DUMMY, LO\_CRYPT\_SKIPJACK, or (since Linux 2.6.0) LO\_CRYPT\_CRYPTOAPI.

The lo\_flags field is a bit mask that can include zero or more of the following:

LO\_FLAGS\_READ\_ONLY

The loopback device is read-only.

LO\_FLAGS\_AUTOCLEAR (since Linux 2.6.25)

The loopback device will autodestruct on last close.

LO\_FLAGS\_PARTSCAN (since Linux 3.2)

Allow automatic partition scanning.

LO\_FLAGS\_DIRECT\_IO (since Linux 4.10)

Use direct I/O mode to access the backing file.

The only lo\_flags that can be modified by LOOP\_SET\_STATUS are LO\_FLAGS\_AUTOCLEAR

and LO\_FLAGS\_PARTSCAN.

# LOOP\_GET\_STATUS

Get the status of the loop device. The (third) ioctl(2) argument must be a pointer to a struct loop\_info.

LOOP\_CHANGE\_FD (since Linux 2.6.5)

Switch the backing store of the loop device to the new file identified file de? scriptor specified in the (third) ioctl(2) argument, which is an integer. This op? eration is possible only if the loop device is read-only and the new backing store is the same size and type as the old backing store.

# LOOP\_SET\_CAPACITY (since Linux 2.6.30)

Resize a live loop device. One can change the size of the underlying backing store and then use this operation so that the loop driver learns about the new size. This operation takes no argument.

# LOOP\_SET\_DIRECT\_IO (since Linux 4.10)

Set DIRECT I/O mode on the loop device, so that it can be used to open backing file. The (third) ioctl(2) argument is an unsigned long value. A nonzero repre? sents direct I/O mode.

# LOOP\_SET\_BLOCK\_SIZE (since Linux 4.14)

Set the block size of the loop device. The (third) ioctl(2) argument is an un? signed long value. This value must be a power of two in the range [512,pagesize]; otherwise, an EINVAL error results.

# LOOP\_CONFIGURE (since Linux 5.8)

Setup and configure all loop device parameters in a single step using the (third) ioctl(2) argument. This argument is a pointer to a loop\_config structure, defined in linux/loop.h> as:

struct loop\_config {

\_\_\_u32 fd;

\_\_u32 block\_size;

struct loop\_info64 info;

\_\_u64 \_\_reserved[8];

};

to do the following:

- \* set the correct block size immediately by setting loop\_config.block\_size;
- \* explicitly request direct I/O mode by setting LO\_FLAGS\_DIRECT\_IO in loop\_con? fig.info.lo\_flags; and
- \* explicitly request read-only mode by setting LO\_FLAGS\_READ\_ONLY in loop\_con? fig.info.lo\_flags.

Since Linux 2.6, there are two new ioctl(2) operations:

#### LOOP\_SET\_STATUS64, LOOP\_GET\_STATUS64

These are similar to LOOP\_SET\_STATUS and LOOP\_GET\_STATUS described above but use the loop\_info64 structure, which has some additional fields and a larger range for some other fields:

struct loop\_info64 {

uint64_t lo_device; /* ioc	ctl r/o */
uint64_t lo_inode; /* ioc	:tl r/o */
uint64_t lo_rdevice; /* iod	ctl r/o */
uint64_t lo_offset;	
uint64_t lo_sizelimit; /* bytes, 0 == max available */	
uint32_t lo_number; /* ic	octl r/o */
uint32_t lo_encrypt_type;	
uint32_t lo_encrypt_key_size; /* ioctl w/o */	
uint32_t lo_flags; i /* ioct	l r/w (r/o before
Linux 2.6.25) */	
uint8_t lo_file_name[LO_NAME_SIZE];	
uint8_t lo_crypt_name[LO_NAME_SIZE];	
uint8_t lo_encrypt_key[LO_KEY_SIZE]; /* ioctl w/o */	
uint64_t lo_init[2];	

```
};
```

#### /dev/loop-control

Since Linux 3.1, the kernel provides the /dev/loop-control device, which permits an appli? cation to dynamically find a free device, and to add and remove loop devices from the sys? tem. To perform these operations, one first opens /dev/loop-control and then employs one of the following ioctl(2) operations:

LOOP\_CTL\_GET\_FREE

Allocate or find a free loop device for use. On success, the device number is re? turned as the result of the call. This operation takes no argument.

#### LOOP\_CTL\_ADD

Add the new loop device whose device number is specified as a long integer in the third ioctl(2) argument. On success, the device index is returned as the result of the call. If the device is already allocated, the call fails with the error EEX? IST.

# LOOP\_CTL\_REMOVE

Remove the loop device whose device number is specified as a long integer in the third ioctl(2) argument. On success, the device number is returned as the result of the call. If the device is in use, the call fails with the error EBUSY.

#### FILES

#### /dev/loop\*

The loop block special device files.

#### EXAMPLES

The program below uses the /dev/loop-control device to find a free loop device, opens the loop device, opens a file to be used as the underlying storage for the device, and then associates the loop device with the backing store. The following shell session demon? strates the use of the program:

\$ dd if=/dev/zero of=file.img bs=1MiB count=10

10+0 records in

10+0 records out

10485760 bytes (10 MB) copied, 0.00609385 s, 1.7 GB/s

\$ sudo ./mnt\_loop file.img

loopname = /dev/loop5

#### Program source

#include <fcntl.h>

#include <linux/loop.h>

#include <sys/ioctl.h>

#include <stdio.h>
