

## ***Red Hat Enterprise Linux Release 9.2 Manual Pages on 'chown.2' command***

**\$ man chown.2**

CHOWN(2)                   Linux Programmer's Manual                   CHOWN(2)

NAME

chown, fchown, lchown, fchownat - change ownership of a file

SYNOPSIS

```
#include <unistd.h>

int chown(const char *pathname, uid_t owner, gid_t group);

int fchown(int fd, uid_t owner, gid_t group);

int lchown(const char *pathname, uid_t owner, gid_t group);

#include <fcntl.h>       /* Definition of AT_* constants */

#include <unistd.h>

int fchownat(int dirfd, const char *pathname,
             uid_t owner, gid_t group, int flags);
```

Feature Test Macro Requirements for glibc (see feature\_test\_macros(7)):

```
fchown(), lchown():

/* Since glibc 2.12: */ _POSIX_C_SOURCE >= 200809L

|| _XOPEN_SOURCE >= 500

/* Glibc versions <= 2.19: */ _BSD_SOURCE
```

fchownat():

Since glibc 2.10:

```
_POSIX_C_SOURCE >= 200809L
```

Before glibc 2.10:

```
_ATFILE_SOURCE
```

DESCRIPTION

These system calls change the owner and group of a file. The `chown()`, `fchown()`, and `lchown()` system calls differ only in how the file is specified:

- \* `chown()` changes the ownership of the file specified by pathname, which is dereferenced if it is a symbolic link.

- \* `fchown()` changes the ownership of the file referred to by the open file descriptor `fd`.

- \* `lchown()` is like `chown()`, but does not dereference symbolic links.

Only a privileged process (Linux: one with the `CAP_CHOWN` capability) may change the owner of a file. The owner of a file may change the group of the file to any group of which that owner is a member. A privileged process (Linux: with `CAP_CHOWN`) may change the group arbitrarily.

If the owner or group is specified as `-1`, then that ID is not changed.

When the owner or group of an executable file is changed by an unprivileged user, the `S_ISUID` and `S_ISGID` mode bits are cleared. POSIX does not specify whether this also should happen when root does the `chown()`; the Linux behavior depends on the kernel version, and since Linux 2.2.13, root is treated like other users. In case of a non-group-executable file (i.e., one for which the `S_IXGRP` bit is not set) the `S_ISGID` bit indicates mandatory locking, and is not cleared by a `chown()`.

When the owner or group of an executable file is changed (by any user), all capability sets for the file are cleared.

#### `fchownat()`

The `fchownat()` system call operates in exactly the same way as `chown()`, except for the differences described here.

If the pathname given in `pathname` is relative, then it is interpreted relative to the directory referred to by the file descriptor `dirfd` (rather than relative to the current working directory of the calling process, as is done by `chown()` for a relative pathname).

If `pathname` is relative and `dirfd` is the special value `AT_FDCWD`, then `pathname` is interpreted relative to the current working directory of the calling process (like `chown()`).

If `pathname` is absolute, then `dirfd` is ignored.

The `flags` argument is a bit mask created by ORing together 0 or more of the following values;

`AT_EMPTY_PATH` (since Linux 2.6.39)

If `pathname` is an empty string, operate on the file referred to by `dirfd` (which may have been obtained using the `open(2)` `O_PATH` flag). In this case, `dirfd` can refer to any type of file, not just a directory. If `dirfd` is `AT_FDCWD`, the call operates on the current working directory. This flag is Linux-specific; define `_GNU_SOURCE` to obtain its definition.

`AT_SYMLINK_NOFOLLOW`

If `pathname` is a symbolic link, do not dereference it: instead operate on the link itself, like `lchown()`. (By default, `fchownat()` dereferences symbolic links, like `chown()`.)

See `openat(2)` for an explanation of the need for `fchownat()`.

## RETURN VALUE

On success, zero is returned. On error, -1 is returned, and `errno` is set appropriately.

## ERRORS

Depending on the filesystem, errors other than those listed below can be returned.

The more general errors for `chown()` are listed below.

`EACCES` Search permission is denied on a component of the `path` prefix.

(See also `path_resolution(7)`.)

`EFAULT` `pathname` points outside your accessible address space.

`ELOOP` Too many symbolic links were encountered in resolving `pathname`.

`ENAMETOOLONG`

`pathname` is too long.

`ENOENT` The file does not exist.

`ENOMEM` Insufficient kernel memory was available.

`ENOTDIR`

A component of the `path` prefix is not a directory.

`EPERM` The calling process did not have the required permissions (see

above) to change owner and/or group.

EPERM The file is marked immutable or append-only. (See `ioctl_iflags(2)`.)

EROFS The named file resides on a read-only filesystem.

The general errors for `fchown()` are listed below:

EBADF `fd` is not a valid open file descriptor.

EIO A low-level I/O error occurred while modifying the inode.

ENOENT See above.

EPERM See above.

EROFS See above.

The same errors that occur for `chown()` can also occur for `fchownat()`.

The following additional errors can occur for `fchownat()`:

EBADF `dirfd` is not a valid file descriptor.

EINVAL Invalid flag specified in `flags`.

ENOTDIR

`pathname` is relative and `dirfd` is a file descriptor referring to a file other than a directory.

## VERSIONS

`fchownat()` was added to Linux in kernel 2.6.16; library support was added to glibc in version 2.4.

## CONFORMING TO

`chown()`, `fchown()`, `lchown()`: 4.4BSD, SVr4, POSIX.1-2001, POSIX.1-2008.

The 4.4BSD version can be used only by the superuser (that is, ordinary users cannot give away files).

`fchownat()`: POSIX.1-2008.

## NOTES

### Ownership of new files

When a new file is created (by, for example, `open(2)` or `mkdir(2)`), its owner is made the same as the filesystem user ID of the creating process. The group of the file depends on a range of factors, including the type of filesystem, the options used to mount the filesystem, and whether or not the set-group-ID mode bit is enabled on the parent directory. If the filesystem supports the `-o grpuid` (or, synonymously

-o BSDgroups) and -o nogroupid (or, synonymously -o sysvgroups) mount(8) options, then the rules are as follows:

- \* If the filesystem is mounted with -o groupid, then the group of a new file is made the same as that of the parent directory.
- \* If the filesystem is mounted with -o nogroupid and the set-group-ID bit is disabled on the parent directory, then the group of a new file is made the same as the process's filesystem GID.
- \* If the filesystem is mounted with -o nogroupid and the set-group-ID bit is enabled on the parent directory, then the group of a new file is made the same as that of the parent directory.

As at Linux 4.12, the -o groupid and -o nogroupid mount options are supported by ext2, ext3, ext4, and XFS. Filesystems that don't support these mount options follow the -o nogroupid rules.

#### Glibc notes

On older kernels where `fchownat()` is unavailable, the glibc wrapper function falls back to the use of `chown()` and `lchown()`. When `pathname` is a relative pathname, glibc constructs a pathname based on the symbolic link in `/proc/self/fd` that corresponds to the `dirfd` argument.

#### NFS

The `chown()` semantics are deliberately violated on NFS filesystems which have UID mapping enabled. Additionally, the semantics of all system calls which access the file contents are violated, because `chown()` may cause immediate access revocation on already open files. Client side caching may lead to a delay between the time where ownership have been changed to allow access for a user and the time where the file can actually be accessed by the user on other clients.

#### Historical details

The original Linux `chown()`, `fchown()`, and `lchown()` system calls supported only 16-bit user and group IDs. Subsequently, Linux 2.4 added `chown32()`, `fchown32()`, and `lchown32()`, supporting 32-bit IDs. The glibc `chown()`, `fchown()`, and `lchown()` wrapper functions transparently deal with the variations across kernel versions.

In versions of Linux prior to 2.1.81 (and distinct from 2.1.46),

chown() did not follow symbolic links. Since Linux 2.1.81, chown() does follow symbolic links, and there is a new system call lchown() that does not follow symbolic links. Since Linux 2.1.86, this new call (that has the same semantics as the old chown()) has got the same syscall number, and chown() got the newly introduced number.

## EXAMPLES

The following program changes the ownership of the file named in its second command-line argument to the value specified in its first command-line argument. The new owner can be specified either as a numeric user ID, or as a username (which is converted to a user ID by using getpwnam(3) to perform a lookup in the system password file).

### Program source

```
#include <pwd.h>
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int
main(int argc, char *argv[])
{
    uid_t uid;
    struct passwd *pwd;
    char *endptr;
    if (argc != 3 || argv[1][0] == '\0') {
        fprintf(stderr, "%s <owner> <file>\n", argv[0]);
        exit(EXIT_FAILURE);
    }
    uid = strtol(argv[1], &endptr, 10); /* Allow a numeric string */
    if (*endptr != '\0') { /* Was not pure numeric string */
        pwd = getpwnam(argv[1]); /* Try getting UID for username */
        if (pwd == NULL) {
            perror("getpwnam");
            exit(EXIT_FAILURE);
        }
    }
}
```

```
    uid = pwd->pw_uid;
}
if (chown(argv[2], uid, -1) == -1) {
    perror("chown");
    exit(EXIT_FAILURE);
}
exit(EXIT_SUCCESS);
}
```
