\$ man dladdr.3

DLADDR(3)

Linux Programmer's Manual

DLADDR(3)

NAME

dladdr, dladdr1 - translate address to symbolic information

SYNOPSIS

#define _GNU_SOURCE

#include <dlfcn.h>

int dladdr(void *addr, Dl_info *info);

int dladdr1(void *addr, Dl_info *info, void **extra_info, int flags);

Link with -ldl.

DESCRIPTION

The function dladdr() determines whether the address specified in addr is located in one of the shared objects loaded by the calling applica? tion. If it is, then dladdr() returns information about the shared ob? ject and symbol that overlaps addr. This information is returned in a DI_info structure:

```
typedef struct {
```

const char *dli_fname; /* Pathname of shared object that

contains address */

void *dli_fbase; /* Base address at which shared

object is loaded */

const char *dli_sname; /* Name of symbol whose definition

overlaps addr */

void *dli_saddr; /* Exact address of symbol named

```
in dli sname */
```

```
} DI_info;
```

If no symbol matching addr could be found, then dli_sname and dli_saddr are set to NULL.

The function dladdr1() is like dladdr(), but returns additional infor? mation via the argument extra_info. The information returned depends on the value specified in flags, which can have one of the following values:

```
RTLD_DL_LINKMAP
```

```
Obtain a pointer to the link map for the matched file. The ex?
tra_info argument points to a pointer to a link_map structure
(i.e., struct link_map **), defined in <link.h> as:
  struct link_map {
     ElfW(Addr) I_addr; /* Difference between the
                   address in the ELF file and
                   the address in memory */
     char
             *I_name; /* Absolute pathname where
                   object was found */
     ElfW(Dyn) *I_Id; /* Dynamic section of the
                   shared object */
     struct link_map *l_next, *l_prev;
                 /* Chain of loaded objects */
     /* Plus additional fields private to the
       implementation */
  };
```

RTLD DL SYMENT

Obtain a pointer to the ELF symbol table entry of the matching symbol. The extra_info argument is a pointer to a symbol pointer: const ElfW(Sym) **. The ElfW() macro definition turns its argument into the name of an ELF data type suitable for the hardware architecture. For example, on a 64-bit platform, ElfW(Sym) yields the data type name Elf64_Sym, which is defined in <elf.h> as:

```
typedef struct {
    Elf64 Word st name; /* Symbol name */
    unsigned char st_info; /* Symbol type and binding */
    unsigned char st_other; /* Symbol visibility */
    Elf64_Section st_shndx; /* Section index */
    Elf64_Addr st_value; /* Symbol value */
                           /* Symbol size */
    Elf64_Xword st_size;
  } Elf64_Sym;
The st name field is an index into the string table.
The st_info field encodes the symbol's type and binding. The
type can be extracted using the macro ELF64_ST_TYPE(st_info) (or
ELF32_ST_TYPE() on 32-bit platforms), which yields one of the
following values:
  Value
              Description
  STT_NOTYPE
                   Symbol type is unspecified
  STT_OBJECT
                   Symbol is a data object
  STT_FUNC
                 Symbol is a code object
  STT SECTION
                   Symbol associated with a section
  STT_FILE
                Symbol's name is filename
  STT_COMMON
                    Symbol is a common data object
  STT_TLS
                Symbol is thread-local data object
  STT_GNU_IFUNC Symbol is indirect code object
The symbol binding can be extracted from the st_info field using
the macro ELF64_ST_BIND(st_info) (or ELF32_ST_BIND() on 32-bit
platforms), which yields one of the following values:
  Value
              Description
  STB_LOCAL
                   Local symbol
  STB_GLOBAL
                    Global symbol
  STB_WEAK
                   Weak symbol
  STB_GNU_UNIQUE Unique symbol
The st_other field contains the symbol's visibility, which can
be extracted using the macro ELF64_ST_VISIBILITY(st_info) (or
```

ELF32_ST_VISIBILITY() on 32-bit platforms), which yields one of

the following values:

Value Description

STV_DEFAULT Default symbol visibility rules

STV_INTERNAL Processor-specific hidden class

STV_HIDDEN Symbol unavailable in other modules

STV_PROTECTED Not preemptible, not exported

RETURN VALUE

On success, these functions return a nonzero value. If the address specified in addr could be matched to a shared object, but not to a symbol in the shared object, then the info->dli_sname and info->dli saddr fields are set to NULL.

If the address specified in addr could not be matched to a shared ob? ject, then these functions return 0. In this case, an error message is not available via dlerror(3).

VERSIONS

dladdr() is present in glibc 2.0 and later. dladdr1() first appeared in glibc 2.3.3.

ATTRIBUTES

For an explanation of the terms used in this section, see at? tributes(7).

?Interface ? Attribute ? Value ?

?dladdr(), dladdr1() ? Thread safety ? MT-Safe ?

CONFORMING TO

These functions are nonstandard GNU extensions that are also present on Solaris.

BUGS

Sometimes, the function pointers you pass to dladdr() may surprise you. On some architectures (notably i386 and x86-64), dli_fname and dli_fbase may end up pointing back at the object from which you called dladdr(), even if the function used as an argument should come from a

dynamically linked library.

The problem is that the function pointer will still be resolved at com? pile time, but merely point to the plt (Procedure Linkage Table) sec? tion of the original object (which dispatches the call after asking the dynamic linker to resolve the symbol). To work around this, you can try to compile the code to be position-independent: then, the compiler cannot prepare the pointer at compile time any more and gcc(1) will generate code that just loads the final symbol address from the got (Global Offset Table) at run time before passing it to dladdr().
