# Red Hat Enterprise Linux Release 9.2 Manual Pages on 'mkfifoat.3' command

## \$ man mkfifoat.3

MKFIFO(3) Linux Programmer's Manual MKFIFO(3) NAME mkfifo, mkfifoat - make a FIFO special file (a named pipe) **SYNOPSIS** #include <sys/types.h> #include <sys/stat.h> int mkfifo(const char \*pathname, mode\_t mode); /\* Definition of AT \* constants \*/ #include <fcntl.h> #include <sys/stat.h> int mkfifoat(int dirfd, const char \*pathname, mode\_t mode); Feature Test Macro Requirements for glibc (see feature\_test\_macros(7)): mkfifoat(): Since glibc 2.10: \_POSIX\_C\_SOURCE >= 200809L Before glibc 2.10: ATFILE SOURCE

#### **DESCRIPTION**

mkfifo() makes a FIFO special file with name pathname. mode specifies the FIFO's permissions. It is modified by the process's umask in the usual way: the permissions of the created file are (mode & ~umask). A FIFO special file is similar to a pipe, except that it is created in a different way. Instead of being an anonymous communications channel, a FIFO special file is entered into the filesystem by calling mkfifo().

Once you have created a FIFO special file in this way, any process can open it for reading or writing, in the same way as an ordinary file. However, it has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks until some other process opens the same FIFO for writing, and vice versa. See fifo(7) for nonblocking handling of FIFO special files.

## mkfifoat()

The mkfifoat() function operates in exactly the same way as mkfifo(), except for the differences described here.

If the pathname given in pathname is relative, then it is interpreted relative to the directory referred to by the file descriptor dirfd (rather than relative to the current working directory of the calling process, as is done by mkfifo() for a relative pathname).

If pathname is relative and dirfd is the special value AT\_FDCWD, then pathname is interpreted relative to the current working directory of

If pathname is absolute, then dirfd is ignored.

the calling process (like mkfifo()).

### **RETURN VALUE**

On success mkfifo() and mkfifoat() return 0. In the case of an error,

-1 is returned (in which case, errno is set appropriately).

## **ERRORS**

EACCES One of the directories in pathname did not allow search (exe? cute) permission.

EDQUOT The user's quota of disk blocks or inodes on the filesystem has been exhausted.

EEXIST pathname already exists. This includes the case where pathname is a symbolic link, dangling or not.

### **ENAMETOOLONG**

Either the total length of pathname is greater than PATH\_MAX, or an individual filename component has a length greater than NAME\_MAX. In the GNU system, there is no imposed limit on over? all filename length, but some filesystems may place limits on

the length of a component.

ENOENT A directory component in pathname does not exist or is a dan? gling symbolic link.

ENOSPC The directory or filesystem has no room for the new file.

#### **ENOTDIR**

A component used as a directory in pathname is not, in fact, a directory.

EROFS pathname refers to a read-only filesystem.

The following additional errors can occur for mkfifoat():

EBADF dirfd is not a valid file descriptor.

#### **ENOTDIR**

pathname is a relative path and dirfd is a file descriptor re? ferring to a file other than a directory.

### **VERSIONS**

mkfifoat() was added to glibc in version 2.4. It is implemented using mknodat(2), available on Linux since kernel 2.6.16.

## **ATTRIBUTES**

For an explanation of the terms used in this section, see at? tributes(7).

?Interface ? Attribute ? Value ?

?mkfifo(), mkfifoat() ? Thread safety ? MT-Safe ?

### **CONFORMING TO**

mkfifo(): POSIX.1-2001, POSIX.1-2008.

mkfifoat(): POSIX.1-2008.

### SEE ALSO

mkfifo(1), close(2), open(2), read(2), stat(2), umask(2), write(2), fifo(7)
