

Red Hat Enterprise Linux Release 9.2 Manual Pages on 'pathconf.3' command

\$ man pathconf.3

FPATHCONF(3) Linux Programmer's Manual FPATHCONF(3)

NAME

fpathconf, pathconf - get configuration values for files

SYNOPSIS

```
#include <unistd.h>

long fpathconf(int fd, int name);

long pathconf(const char *path, int name);
```

DESCRIPTION

fpathconf() gets a value for the configuration option name for the open file descriptor fd.

pathconf() gets a value for configuration option name for the filename path.

The corresponding macros defined in <unistd.h> are minimum values; if an application wants to take advantage of values which may change, a call to fpathconf() or pathconf() can be made, which may yield more liberal results.

Setting name equal to one of the following constants returns the fol?

lowing configuration options:

`_PC_LINK_MAX`

The maximum number of links to the file. If fd or path refer to a directory, then the value applies to the whole directory. The corresponding macro is `_POSIX_LINK_MAX`.

`_PC_MAX_CANON`

The maximum length of a formatted input line, where `fd` or `path` must refer to a terminal. The corresponding macro is `_POSIX_MAX_CANON`.

`_PC_MAX_INPUT`

The maximum length of an input line, where `fd` or `path` must refer to a terminal. The corresponding macro is `_POSIX_MAX_INPUT`.

`_PC_NAME_MAX`

The maximum length of a filename in the directory `path` or `fd` that the process is allowed to create. The corresponding macro is `_POSIX_NAME_MAX`.

`_PC_PATH_MAX`

The maximum length of a relative pathname when `path` or `fd` is the current working directory. The corresponding macro is `_POSIX_PATH_MAX`.

`_PC_PIPE_BUF`

The maximum number of bytes that can be written atomically to a pipe or FIFO. For `fpathconf()`, `fd` should refer to a pipe or FIFO. For `pathconf()`, `path` should refer to a FIFO or a directory; in the latter case, the returned value corresponds to FIFOs created in that directory. The corresponding macro is `_POSIX_PIPE_BUF`.

`_PC_CHOWN_RESTRICTED`

This returns a positive value if the use of `chown(2)` and `fchown(2)` for changing a file's user ID is restricted to a process with appropriate privileges, and changing a file's group ID to a value other than the process's effective group ID or one of its supplementary group IDs is restricted to a process with appropriate privileges. According to POSIX.1, this variable shall always be defined with a value other than -1. The corresponding macro is `_POSIX_CHOWN_RESTRICTED`.

If `fd` or `path` refers to a directory, then the return value applies to all files in that directory.

`_PC_NO_TRUNC`

This returns nonzero if accessing filenames longer than `_POSIX_NAME_MAX` generates an error. The corresponding macro is `_POSIX_NO_TRUNC`.

`_PC_VDISABLE`

This returns nonzero if special character processing can be disabled, where `fd` or `path` must refer to a terminal.

RETURN VALUE

The return value of these functions is one of the following:

- * On error, -1 is returned and `errno` is set to indicate the cause of the error (for example, `EINVAL`, indicating that name is invalid).
- * If name corresponds to a maximum or minimum limit, and that limit is indeterminate, -1 is returned and `errno` is not changed. (To distinguish an indeterminate limit from an error, set `errno` to zero before the call, and then check whether `errno` is nonzero when -1 is returned.)
- * If name corresponds to an option, a positive value is returned if the option is supported, and -1 is returned if the option is not supported.
- * Otherwise, the current value of the option or limit is returned.

This value will not be more restrictive than the corresponding value that was described to the application in `<unistd.h>` or `<limits.h>` when the application was compiled.

ERRORS

`EACCES` (`pathconf()`) Search permission is denied for one of the directories in the path prefix of `path`.

`EBADF` (`fpathconf()`) `fd` is not a valid file descriptor.

`EINVAL` name is invalid.

`EINVAL` The implementation does not support an association of name with the specified file.

`ELOOP` (`pathconf()`) Too many symbolic links were encountered while resolving path.

`ENAMETOOLONG`

(`pathconf()`) path is too long.

ENOENT (pathconf()) A component of path does not exist, or path is an empty string.

ENOTDIR

(pathconf()) A component used as a directory in path is not in fact a directory.

ATTRIBUTES

For an explanation of the terms used in this section, see attributes(7).

??

?Interface ? Attribute ? Value ?

??

?pathconf(), pathconf() ? Thread safety ? MT-Safe ?

??

CONFORMING TO

POSIX.1-2001, POSIX.1-2008.

NOTES

Files with name lengths longer than the value returned for name equal to _PC_NAME_MAX may exist in the given directory.

Some returned values may be huge; they are not suitable for allocating memory.
