## **Red Hat Enterprise Linux Release 9.2 Manual Pages on 'sudo-ldap.conf.5' command**

### **\$ man sudo-ldap.conf.5**

SUDOERS.LDAP(5)      BSD File Formats Manual      SUDOERS.LDAP(5)

#### NAME

sudoers.ldap ? sudo LDAP configuration

#### DESCRIPTION

In addition to the standard sudoers file, sudo may be configured via LDAP. This can be especially useful for synchronizing sudoers in a large, distributed environment.

Using LDAP for sudoers has several benefits:

? sudo no longer needs to read sudoers in its entirety. When LDAP is used, there are only two or three LDAP queries per invocation. This makes it especially fast and particularly usable in LDAP environments.

? sudo no longer exits if there is a typo in sudoers. It is not possible to load LDAP data into the server that does not conform to the sudoers schema, so proper syntax is guaranteed. It is still possible to have typos in a user or host name, but this will not prevent sudo from running.

? It is possible to specify per-entry options that override the global default options. /etc/sudoers only supports default options and limited options associated with user/host/commands/aliases. The syntax is complicated and can be difficult for users to understand. Placing the options directly in the entry is more natural.

? The visudo program is no longer needed. visudo provides locking and syntax checking of the /etc/sudoers file. Since LDAP updates are

atomic, locking is no longer necessary. Because syntax is checked when the data is inserted into LDAP, there is no need for a specialized tool to check syntax.

## SUDOers LDAP container

The sudoers configuration is contained in the ou=SUDOers LDAP container.

Sudo first looks for the cn=defaults entry in the SUDOers container. If found, the multi-valued sudoOption attribute is parsed in the same manner as a global Defaults line in /etc/sudoers. In the following example, the SSH\_AUTH\_SOCK variable will be preserved in the environment for all users.

```
dn: cn=defaults,ou=SUDOers,dc=my-domain,dc=com
objectClass: top
objectClass: sudoRole
cn: defaults
description: Default sudoOption's go here
sudoOption: env_keep+=SSH_AUTH_SOCK
```

The equivalent of a sudoer in LDAP is a sudoRole. It consists of the following attributes:

### sudoUser

A user name, user-ID (prefixed with ?#?), Unix group name or ID (prefixed with ?%? or ?%#? respectively), user netgroup (prefixed with ?+?), or non-Unix group name or ID (prefixed with ?%:? or ?%:#? respectively). User netgroups are matched using the user and domain members only; the host member is not used when matching. Non-Unix group support is only available when an appropriate group\_plugin is defined in the global defaults sudoRole object.

### sudoHost

A host name, IP address, IP network, or host netgroup (prefixed with a ?+?). The special value ALL will match any host. Host netgroups are matched using the host (both qualified and unqualified) and domain members only; the user member is not used when matching. If a sudoHost entry is preceded by an exclamation point, !?!, and the entry matches, the sudoRole in which it resides will be ig?

nored. Negated sudoHost entries are only supported by version 1.8.18 or higher.

#### sudoCommand

A fully-qualified Unix command name with optional command line arguments, potentially including globbing characters (aka wild cards). If a command name is preceded by an exclamation point, !?, the user will be prohibited from running that command.

The built-in command ?sudoedit? is used to permit a user to run sudo with the -e option (or as sudoedit). It may take command line arguments just as a normal command does. Note that ?sudoedit? is a command built into sudo itself and must be specified in without a leading path.

The special value ALL will match any command.

If a command name is prefixed with a SHA-2 digest, it will only be allowed if the digest matches. This may be useful in situations where the user invoking sudo has write access to the command or its parent directory. The following digest formats are supported:

sha224, sha256, sha384 and sha512. The digest name must be followed by a colon (?:?) and then the actual digest, in either hex or base64 format. For example, given the following value for sudoCommand:

```
sha224:0GomF8mNN3wIDt1HD9XldjJ3SNgpFdbjO1+Nsq /bin/lS
```

The user may only run /bin/lS if its sha224 digest matches the specified value. Command digests are only supported by version 1.8.7 or higher.

#### sudoOption

Identical in function to the global options described above, but specific to the sudoRole in which it resides.

#### sudoRunAsUser

A user name or uid (prefixed with ?#?) that commands may be run as or a Unix group (prefixed with a ?%?) or user netgroup (prefixed with a ?+?) that contains a list of users that commands may be run as. The special value ALL will match any user. If a sudoRunAsUser

entry is preceded by an exclamation point, `#!`, and the entry matches, the `sudoRole` in which it resides will be ignored. If `sudoRunAsUser` is specified but empty, it will match the invoking user. If neither `sudoRunAsUser` nor `sudoRunAsGroup` are present, the value of the `runas_default` `sudoOption` is used (defaults to `root`).

The `sudoRunAsUser` attribute is only available in `sudo` versions 1.7.0 and higher. Older versions of `sudo` use the `sudoRunAs` attribute instead. Negated `sudoRunAsUser` entries are only supported by version 1.8.26 or higher.

#### `sudoRunAsGroup`

A Unix group or gid (prefixed with `#`) that commands may be run as. The special value `ALL` will match any group. If a `sudoRunAsGroup` entry is preceded by an exclamation point, `#!`, and the entry matches, the `sudoRole` in which it resides will be ignored.

The `sudoRunAsGroup` attribute is only available in `sudo` versions 1.7.0 and higher. Negated `sudoRunAsGroup` entries are only supported by version 1.8.26 or higher.

#### `sudoNotBefore`

A timestamp in the form `yyyymmddHHMMSSZ` that can be used to provide a start date/time for when the `sudoRole` will be valid. If multiple `sudoNotBefore` entries are present, the earliest is used. Note that timestamps must be in Coordinated Universal Time (UTC), not the local timezone. The minute and seconds portions are optional, but some LDAP servers require that they be present (contrary to the RFC).

The `sudoNotBefore` attribute is only available in `sudo` versions 1.7.5 and higher and must be explicitly enabled via the `SUDOERS_TIMED` option in `/etc/sudo-ldap.conf`.

#### `sudoNotAfter`

A timestamp in the form `yyyymmddHHMMSSZ` that indicates an expiration date/time, after which the `sudoRole` will no longer be valid. If multiple `sudoNotAfter` entries are present, the last one is used.

Note that timestamps must be in Coordinated Universal Time (UTC), not the local timezone. The minute and seconds portions are optional, but some LDAP servers require that they be present (contrary to the RFC).

The sudoNotAfter attribute is only available in sudo versions 1.7.5 and higher and must be explicitly enabled via the SUDOERS\_TIMED option in /etc/sudo-ldap.conf.

#### sudoOrder

The sudoRole entries retrieved from the LDAP directory have no inherent order. The sudoOrder attribute is an integer (or floating point value for LDAP servers that support it) that is used to sort the matching entries. This allows LDAP-based sudoers entries to more closely mimic the behavior of the sudoers file, where the order of the entries influences the result. If multiple entries match, the entry with the highest sudoOrder attribute is chosen. This corresponds to the "last match" behavior of the sudoers file. If the sudoOrder attribute is not present, a value of 0 is assumed. The sudoOrder attribute is only available in sudo versions 1.7.5 and higher.

Each attribute listed above should contain a single value, but there may be multiple instances of each attribute type. A sudoRole must contain at least one sudoUser, sudoHost and sudoCommand.

The following example allows users in group wheel to run any command on any host via sudo:

```
dn: cn=%wheel,ou=SUDOers,dc=my-domain,dc=com
objectClass: top
objectClass: sudoRole
cn: %wheel
sudoUser: %wheel
sudoHost: ALL
sudoCommand: ALL
```

#### Anatomy of LDAP sudoers lookup

When looking up a sudoer using LDAP there are only two or three LDAP

queries per invocation. The first query is to parse the global options.

The second is to match against the user's name and the groups that the user belongs to. (The special ALL tag is matched in this query too.) If no match is returned for the user's name and groups, a third query returns all entries containing user netgroups and other non-Unix groups and checks to see if the user belongs to any of them.

If timed entries are enabled with the SUDOERS\_TIMED configuration directive, the LDAP queries include a sub-filter that limits retrieval to entries that satisfy the time constraints, if any.

If the NETGROUP\_BASE configuration directive is present (see Configuring ldap.conf below), queries are performed to determine the list of netgroups the user belongs to before the sudoers query. This makes it possible to include netgroups in the sudoers query string in the same manner as Unix groups. The third query mentioned above is not performed unless a group provider plugin is also configured. The actual LDAP queries performed by sudo are as follows:

1. Match all nisNetgroup records with a nisNetgroupTriple containing the user, host and NIS domain. The query will match nisNetgroupTriple entries with either the short or long form of the host name or no host name specified in the tuple. If the NIS domain is set, the query will match only match entries that include the domain or for which there is no domain present. If the NIS domain is not set, a wildcard is used to match any domain name but be aware that the NIS schema used by some LDAP servers may not support wildcards for nisNetgroupTriple.
2. Repeated queries are performed to find any nested nisNetgroup records with a memberNisNetgroup entry that refers to an already-matched record.

For sites with a large number of netgroups, using NETGROUP\_BASE can significantly speed up sudo's execution time.

#### Differences between LDAP and non-LDAP sudoers

One of the major differences between LDAP and file-based sudoers is that in LDAP, sudo-specific Aliases are not supported.

For the most part, there is little need for sudo-specific Aliases. Unix groups, non-Unix groups (via the group\_plugin) or user netgroups can be used in place of User\_Aliases and Runas\_Aliases. Host netgroups can be used in place of Host\_Aliases. Since groups and netgroups can also be stored in LDAP there is no real need for sudo-specific aliases.

There are also some subtle differences in the way sudoers is handled once in LDAP. Probably the biggest is that according to the RFC, LDAP ordering is arbitrary and you cannot expect that Attributes and Entries are returned in any specific order.

The order in which different entries are applied can be controlled using the sudoOrder attribute, but there is no way to guarantee the order of attributes within a specific entry. If there are conflicting command rules in an entry, the negative takes precedence. This is called paranoid behavior (not necessarily the most specific match).

Here is an example:

```
# /etc/sudoers:
# Allow all commands except shell
johnny ALL=(root) ALL,!/bin/sh
# Always allows all commands because ALL is matched last
puddles ALL=(root) !/bin/sh,ALL
# LDAP equivalent of johnny
# Allows all commands except shell
dn: cn=role1,ou=Sudoers,dc=my-domain,dc=com
objectClass: sudoRole
objectClass: top
cn: role1
sudoUser: johnny
sudoHost: ALL
sudoCommand: ALL
sudoCommand: !/bin/sh
# LDAP equivalent of puddles
# Notice that even though ALL comes last, it still behaves like
# role1 since the LDAP code assumes the more paranoid configuration
```

```
dn: cn=role2,ou=Sudoers,dc=my-domain,dc=com
```

```
objectClass: sudoRole
```

```
objectClass: top
```

```
cn: role2
```

```
sudoUser: puddles
```

```
sudoHost: ALL
```

```
sudoCommand: !/bin/sh
```

```
sudoCommand: ALL
```

Another difference is that it is not possible to use negation in a su?

doUser, sudoRunAsUser or sudoRunAsGroup attribute. For example, the fol?

lowing attributes do not behave the way one might expect.

```
# does not match all but joe
```

```
# rather, does not match anyone
```

```
sudoUser: !joe
```

```
# does not match all but joe
```

```
# rather, matches everyone including Joe
```

```
sudoUser: ALL
```

```
sudoUser: !joe
```

Converting between file-based and LDAP sudoers

The `cvtsudoers(1)` utility can be used to convert between file-based and LDAP sudoers. However, there are features in the file-based sudoers that have no equivalent in LDAP-based sudoers (and vice versa). These cannot be converted automatically.

For example, a `Cmnd_Alias` in a sudoers file may be converted to a `sudoRole` that contains multiple commands. Multiple users and/or groups may be assigned to the `sudoRole`.

Also, `host`, `user`, `runas` and `command-based Defaults` entries are not supported. However, a `sudoRole` may contain one or more `sudoOption` attributes which can often serve the same purpose.

Consider the following sudoers lines:

```
Cmnd_Alias PAGERS = /usr/bin/more, /usr/bin/pg, /usr/bin/less
```

```
Defaults!PAGERS noexec
```

```
alice, bob ALL = ALL
```

In this example, alice and bob are allowed to run all commands, but the commands listed in PAGERS will have the noexec flag set, preventing shell escapes.

When converting this to LDAP, two sudoRole objects can be used:

```
dn: cn=PAGERS,ou=SUDOers,dc=my-domain,dc=com
```

```
objectClass: top
```

```
objectClass: sudoRole
```

```
cn: PAGERS
```

```
sudoUser: alice
```

```
sudoUser: bob
```

```
sudoHost: ALL
```

```
sudoCommand: /usr/bin/more
```

```
sudoCommand: /usr/bin/pg
```

```
sudoCommand: /usr/bin/less
```

```
sudoOption: noexec
```

```
sudoOrder: 900
```

```
dn: cn=ADMINS,ou=SUDOers,dc=my-domain,dc=com
```

```
objectClass: top
```

```
objectClass: sudoRole
```

```
cn: ADMINS
```

```
sudoUser: alice
```

```
sudoUser: bob
```

```
sudoHost: ALL
```

```
sudoCommand: ALL
```

```
sudoOrder: 100
```

In the LDAP version, the sudoOrder attribute is used to guarantee that the PAGERS sudoRole with noexec has precedence. Unlike the sudoers version, the LDAP version requires that all users for whom the restriction should apply be assigned to the PAGERS sudoRole. Using a Unix group or netgroup in PAGERS rather than listing each user would make this easier to maintain.

Per-user Defaults entries can be emulated by using one or more sudoOption attributes in a sudoRole. Consider the following sudoers lines:

User\_Alias ADMINS = john, sally

Defaults:ADMINS !authenticate

ADMINS ALL = (ALL:ALL) ALL

In this example, john and sally are allowed to run any command as any user or group.

When converting this to LDAP, we can use a Unix group instead of the User\_Alias.

dn: cn=admins,ou=SUDOers,dc=my-domain,dc=com

objectClass: top

objectClass: sudoRole

cn: admins

sudoUser: %admin

sudoHost: ALL

sudoRunAsUser: ALL

sudoRunAsGroup: ALL

sudoCommand: ALL

sudoOption: !authenticate

This assumes that users john and sally are members of the ?admins? Unix group.

#### Sudoers schema

In order to use sudo's LDAP support, the sudo schema must be installed on your LDAP server. In addition, be sure to index the sudoUser attribute.

The sudo distribution includes versions of the sudoers schema for multiple LDAP servers:

#### schema.OpenLDAP

OpenLDAP slapd and OpenBSD Idapd

#### schema.olcSudo

OpenLDAP slapd 2.3 and higher when on-line configuration is enabled

#### schema.iPlanet

Netscape-derived servers such as the iPlanet, Oracle, and 389 Directory Servers

#### schema.ActiveDirectory

Microsoft Active Directory

The schema in OpenLDAP format is also included in the EXAMPLES section.

## Configuring ldap.conf

Sudo reads the `/etc/sudo-ldap.conf` file for LDAP-specific configuration.

Typically, this file is shared between different LDAP-aware clients. As such, most of the settings are not sudo-specific. Note that sudo parses `/etc/sudo-ldap.conf` itself and may support options that differ from those described in the system's `ldap.conf(5)` manual. The path to `ldap.conf` may be overridden via the `ldap_conf` plugin argument in `sudo.conf(5)`.

Also note that on systems using the OpenLDAP libraries, default values specified in `/etc/openldap/ldap.conf` or the user's `.ldaprc` files are not used.

sudo supports a variety of LDAP library implementations, including OpenLDAP, Netscape-derived (also used by Solaris and HP-UX), and IBM LDAP (aka Tivoli). Some options are specific to certain LDAP implementations or have implementation-specific behavior. These differences are noted below where applicable.

Only those options explicitly listed in `/etc/sudo-ldap.conf` as being supported by sudo are honored. Configuration options are listed below in upper case but are parsed in a case-independent manner.

Lines beginning with a pound sign (`##`) are ignored. Leading white space is removed from the beginning of lines.

### `BIND_TIMELIMIT` seconds

The `BIND_TIMELIMIT` parameter specifies the amount of time, in seconds, to wait while trying to connect to an LDAP server. If multiple URIs or HOSTs are specified, this is the amount of time to wait before trying the next one in the list.

### `BINDDN` DN

The `BINDDN` parameter specifies the identity, in the form of a Distinguished Name (DN), to use when performing LDAP operations. If not specified, LDAP operations are performed with an anonymous identity. By default, most LDAP servers will allow anonymous access.

### `BINDPW` secret

The BINDPW parameter specifies the password to use when performing LDAP operations. This is typically used in conjunction with the BINDDN parameter. The secret may be a plain text password or a base64-encoded string with a ?base64:? prefix. For example:

```
    BINDPW base64:dGVzdA==
```

If a plain text password is used, it should be a simple string without quotes. Plain text passwords may not include the comment character (?#?) and the escaping of special characters with a backslash (?\\?) is not supported.

#### DEREF never/searching/finding/always

How alias dereferencing is to be performed when searching. See the ldap.conf(5) manual for a full description of this option.

#### HOST name[:port] ...

If no URI is specified (see below), the HOST parameter specifies a white space-delimited list of LDAP servers to connect to. Each host may include an optional port separated by a colon (?:?). The HOST parameter is deprecated in favor of the URI specification and is included for backward compatibility only.

#### KRB5\_CCNAME file name

The path to the Kerberos 5 credential cache to use when authenticating with the remote server.

This option is only relevant when using SASL authentication (see below).

#### LDAP\_VERSION number

The version of the LDAP protocol to use when connecting to the server. The default value is protocol version 3.

#### NETGROUP\_BASE base

The base DN to use when performing LDAP netgroup queries. Typically this is of the form ou=netgroup,dc=my-domain,dc=com for the domain my-domain.com. Multiple NETGROUP\_BASE lines may be specified, in which case they are queried in the order specified.

This option can be used to query a user's netgroups directly via LDAP which is usually faster than fetching every sudoRole object

containing a sudoUser that begins with a ?+? prefix. The NIS schema used by some LDAP servers need a modification to support querying the nisNetgroup object by its nisNetgroupTriple member.

OpenLDAP's slapd requires the following change to the nisNetgroupTriple attribute:

```
attributetype ( 1.3.6.1.1.1.14 NAME 'nisNetgroupTriple'  
    DESC 'Netgroup triple'  
    EQUALITY caseIgnoreIA5Match  
    SUBSTR caseIgnoreIA5SubstringsMatch  
    SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 )
```

#### NETGROUP\_SEARCH\_FILTER ldap\_filter

An LDAP filter which is used to restrict the set of records returned when performing an LDAP netgroup query. Typically, this is of the form attribute=value or (&(attribute=value)(attribute2=value2)). The default search filter is: objectClass=nisNetgroup. If ldap\_filter is omitted, no search filter will be used.

This option is only used when querying netgroups directly via LDAP.

#### NETWORK\_TIMEOUT seconds

An alias for BIND\_TIMELIMIT provided for OpenLDAP compatibility.

#### PORT port\_number

If no URI is specified, the PORT parameter specifies the default port to connect to on the LDAP server if a HOST parameter does not specify the port itself. If no PORT parameter is used, the default is port 389 for LDAP and port 636 for LDAP over TLS (SSL). The PORT parameter is deprecated in favor of the URI specification and is included for backward compatibility only.

#### ROOTBINDDN DN

The ROOTBINDDN parameter specifies the identity, in the form of a Distinguished Name (DN), to use when performing privileged LDAP operations, such as sudoers queries. The password corresponding to the identity should be stored in the or the path specified by the ldap\_secret plugin argument in sudo.conf(5), which defaults to

/etc/ldap.secret. If no ROOTBINDDN is specified, the BINDDN identity is used (if any).

ROOTUSE\_SASL on/true/yes/off/false/no

Enable ROOTUSE\_SASL to enable SASL authentication when connecting to an LDAP server from a privileged process, such as sudo.

SASL\_AUTH\_ID identity

The SASL user name to use when connecting to the LDAP server. By default, sudo will use an anonymous connection.

This option is only relevant when using SASL authentication.

SASL\_MECH mechanisms

A white space-delimited list of SASL authentication mechanisms to use. By default, sudo will use GSSAPI authentication.

SASL\_SECPROPS none/properties

SASL security properties or none for no properties. See the SASL programmer's manual for details.

This option is only relevant when using SASL authentication.

SSL on/true/yes/off/false/no

If the SSL parameter is set to on, true or yes, TLS (SSL) encryption is always used when communicating with the LDAP server. Typically, this involves connecting to the server on port 636 (ldaps).

SSL start\_tls

If the SSL parameter is set to start\_tls, the LDAP server connection is initiated normally and TLS encryption is begun before the bind credentials are sent. This has the advantage of not requiring a dedicated port for encrypted communications. This parameter is only supported by LDAP servers that honor the start\_tls extension, such as the OpenLDAP and IBM Tivoli Directory servers.

SUDOERS\_BASE base

The base DN to use when performing sudo LDAP queries. Typically this is of the form ou=SUDOers,dc=my-domain,dc=com for the domain my-domain.com. Multiple SUDOERS\_BASE lines may be specified, in which case they are queried in the order specified.

SUDOERS\_DEBUG debug\_level

This sets the debug level for sudo LDAP queries. Debugging information is printed to the standard error. A value of 1 results in a moderate amount of debugging information. A value of 2 shows the results of the matches themselves. This parameter should not be set in a production environment as the extra information is likely to confuse users.

The SUDOERS\_DEBUG parameter is deprecated and will be removed in a future release. The same information is now logged via the sudo debugging framework using the `?ldap?` subsystem at priorities `diag` and `info` for `debug_level` values 1 and 2 respectively. See the `sudo.conf(5)` manual for details on how to configure sudo debugging.

#### SUDOERS\_SEARCH\_FILTER `ldap_filter`

An LDAP filter which is used to restrict the set of records returned when performing a sudo LDAP query. Typically, this is of the form `attribute=value` or `(&(attribute=value)(attribute2=value2))`. The default search filter is: `objectClass=sudoRole`. If `ldap_filter` is omitted, no search filter will be used.

#### SUDOERS\_TIMED `on/true/yes/off/false/no`

Whether or not to evaluate the `sudoNotBefore` and `sudoNotAfter` attributes that implement time-dependent sudoers entries.

#### TIMELIMIT `seconds`

The `TIMELIMIT` parameter specifies the amount of time, in seconds, to wait for a response to an LDAP query.

#### TIMEOUT `seconds`

The `TIMEOUT` parameter specifies the amount of time, in seconds, to wait for a response from the various LDAP APIs.

#### TLS\_CACERT `file name`

An alias for `TLS_CACERTFILE` for OpenLDAP compatibility.

#### TLS\_CACERTFILE `file name`

The path to a certificate authority bundle which contains the certificates for all the Certificate Authorities the client knows to be valid, e.g., `/etc/ssl/ca-bundle.pem`.

This option is only supported by the OpenLDAP libraries. Netscape-derived LDAP libraries use the same certificate database for CA and client certificates (see TLS\_CERT).

#### TLS\_CACERTDIR directory

Similar to TLS\_CACERTFILE but instead of a file, it is a directory containing individual Certificate Authority certificates, e.g., /etc/ssl/certs. The directory specified by TLS\_CACERTDIR is checked after TLS\_CACERTFILE.

This option is only supported by the OpenLDAP libraries.

#### TLS\_CERT file name

The path to a file containing the client certificate which can be used to authenticate the client to the LDAP server. The certificate type depends on the LDAP libraries used.

OpenLDAP:

`tls_cert /etc/ssl/client_cert.pem`

Netscape-derived:

`tls_cert /var/ldap/cert7.db`

IBM LDAP:

Unused, the key database specified by TLS\_KEY contains both keys and certificates.

When using Netscape-derived libraries, this file may also contain Certificate Authority certificates.

#### TLS\_CHECKPEER on/true/yes/off/false/no

If enabled, TLS\_CHECKPEER will cause the LDAP server's TLS certificate to be verified. If the server's TLS certificate cannot be verified (usually because it is signed by an unknown certificate authority), sudo will be unable to connect to it. If TLS\_CHECKPEER is disabled, no check is made. Note that disabling the check creates an opportunity for man-in-the-middle attacks since the server's identity will not be authenticated. If possible, the CA's certificate should be installed locally so it can be verified.

This option is not supported by the IBM LDAP libraries.

#### TLS\_KEY file name

The path to a file containing the private key which matches the certificate specified by TLS\_CERT. The private key must not be password-protected. The key type depends on the LDAP libraries used.

OpenLDAP:

```
tls_key /etc/ssl/client_key.pem
```

Netscape-derived:

```
tls_key /var/ldap/key3.db
```

IBM LDAP:

```
tls_key /usr/ldap/ldapkey.kdb
```

When using IBM LDAP libraries, this file may also contain Certificate Authority and client certificates and may be encrypted.

TLS\_CIPHERS cipher list

The TLS\_CIPHERS parameter allows the administrator to restrict which encryption algorithms may be used for TLS (SSL) connections. See the OpenLDAP or IBM Tivoli Directory Server manual for a list of valid ciphers.

This option is not supported by Netscape-derived libraries.

TLS\_KEYPW secret

The TLS\_KEYPW contains the password used to decrypt the key data? base on clients using the IBM LDAP library. The secret may be a plain text password or a base64-encoded string with a ?base64:? prefix. For example:

```
TLS_KEYPW base64:dGVzdA==
```

If a plain text password is used, it should be a simple string without quotes. Plain text passwords may not include the comment character (?#?) and the escaping of special characters with a backslash (?\\?) is not supported. If this option is used, /etc/sudo-ldap.conf must not be world-readable to avoid exposing the password. Alternately, a stash file can be used to store the password in encrypted form (see below).

If no TLS\_KEYPW is specified, a stash file will be used if it exists. The stash file must have the same path as the file specified

by `TLS_KEY`, but use a `.sth` file extension instead of `.kdb`, e.g., `ldapkey.sth`. The default `ldapkey.kdb` that ships with the IBM Tivoli Directory Server is encrypted with the password `ssl_password`. The `gsk8capicmd` utility can be used to manage the key database and create a stash file.

This option is only supported by the IBM LDAP libraries.

#### `TLS_REQCERT` level

The `TLS_REQCERT` parameter controls how the LDAP server's TLS certificate will be verified (if at all). If the server's TLS certificate cannot be verified (usually because it is signed by an unknown certificate authority), `sudo` will be unable to connect to it.

The following level values are supported:

- `never` The server certificate will not be requested or checked.
- `allow` The server certificate will be requested. A missing or invalid certificate is ignored and not considered an error.
- `try` The server certificate will be requested. A missing certificate is ignored but an invalid certificate will result in a connection error.
- `demand | hard`  
The server certificate will be requested. A missing or invalid certificate will result in a connection error. This is the default behavior.

This option is only supported by the OpenLDAP libraries. Other LDAP libraries only support the `TLS_CHECKPEER` parameter.

#### `TLS_RANDFILE` file name

The `TLS_RANDFILE` parameter specifies the path to an entropy source for systems that lack a random device. It is generally used in conjunction with `prngd` or `egd`.

This option is only supported by the OpenLDAP libraries.

#### URI `ldap[s]://[hostname[:port]] ...`

Specifies a white space-delimited list of one or more URIs describing

ing the LDAP server(s) to connect to. The protocol may be either ldap or ldaps, the latter being for servers that support TLS (SSL) encryption. If no port is specified, the default is port 389 for ldap:// or port 636 for ldaps://. If no hostname is specified, sudo will connect to localhost. Multiple URI lines are treated identically to a URI line containing multiple entries. Only systems using the OpenSSL libraries support the mixing of ldap:// and ldaps:// URIs. Both the Netscape-derived and IBM LDAP libraries used on most commercial versions of Unix are only capable of supporting one or the other.

USE\_SASL on/true/yes/off/false/no

Enable USE\_SASL for LDAP servers that support SASL authentication.

ROOTSASL\_AUTH\_ID identity

The SASL user name to use when ROOTUSE\_SASL is enabled.

See the ldap.conf entry in the EXAMPLES section.

#### Configuring nsswitch.conf

Unless it is disabled at build time, sudo consults the Name Service Switch file, /etc/nsswitch.conf, to specify the sudoers search order.

Sudo looks for a line beginning with sudoers: and uses this to determine the search order. Note that sudo does not stop searching after the first match and later matches take precedence over earlier ones. The following sources are recognized:

files read sudoers from /etc/sudoers

ldap read sudoers from LDAP

In addition, the entry [NOTFOUND=return] will short-circuit the search if the user was not found in the preceding source.

To consult LDAP first followed by the local sudoers file (if it exists), use:

sudoers: ldap files

The local sudoers file can be ignored completely by using:

sudoers: ldap

If the /etc/nsswitch.conf file is not present or there is no sudoers line, the following default is assumed:

sudoers: files

Note that `/etc/nsswitch.conf` is supported even when the underlying operating system does not use an `nsswitch.conf` file, except on AIX (see below).

### Configuring `netshvc.conf`

On AIX systems, the `/etc/netshvc.conf` file is consulted instead of `/etc/nsswitch.conf`. `sudo` simply treats `netshvc.conf` as a variant of `nsswitch.conf`; information in the previous section unrelated to the file format itself still applies.

To consult LDAP first followed by the local sudoers file (if it exists), use:

```
sudoers = ldap, files
```

The local sudoers file can be ignored completely by using:

```
sudoers = ldap
```

To treat LDAP as authoritative and only use the local sudoers file if the user is not present in LDAP, use:

```
sudoers = ldap = auth, files
```

Note that in the above example, the `auth` qualifier only affects user lookups; both LDAP and sudoers will be queried for Defaults entries.

If the `/etc/netshvc.conf` file is not present or there is no sudoers line, the following default is assumed:

```
sudoers = files
```

### Integration with `sssd`

On systems with the System Security Services Daemon (SSSD) and where `sudo` has been built with SSSD support, it is possible to use SSSD to cache LDAP sudoers rules. To use SSSD as the sudoers source, you should use `sss` instead of `ldap` for the sudoers entry in `/etc/nsswitch.conf`. Note that the `/etc/sudo-ldap.conf` file is not used by the SSSD sudo back end. Please see `sssd-sudo(5)` for more information on configuring `sudo` to work with SSSD.

## FILES

`/etc/sudo-ldap.conf` LDAP configuration file

`/etc/nsswitch.conf` determines sudoers source order

/etc/netsvc.conf determines sudoers source order on AIX

## EXAMPLES

### Example ldap.conf

```
# Either specify one or more URIs or one or more host:port pairs.
# If neither is specified sudo will default to localhost, port 389.
#
#host      ldapserver
#host      ldapserver1 ldapserver2:390
#
# Default port if host is specified without one, defaults to 389.
#port      389
#
# URI will override the host and port settings.
uri        ldap://ldapserver
#uri       ldaps://secureldapserver
#uri       ldaps://secureldapserver ldap://ldapserver
#
# The amount of time, in seconds, to wait while trying to connect to
# an LDAP server.
bind_timelimit 30
#
# The amount of time, in seconds, to wait while performing an LDAP query.
timelimit 30
#
# Must be set or sudo will ignore LDAP; may be specified multiple times.
sudoers_base ou=SUDOers,dc=my-domain,dc=com
#
# verbose sudoers matching from ldap
#sudoers_debug 2
#
# Enable support for time-based entries in sudoers.
#sudoers_timed yes
#
```

```
# optional proxy credentials
#binddn    <who to search as>
#bindpw    <password>
#rootbinddn <who to search as, uses /etc/ldap.secret for bindpw>
#
# LDAP protocol version, defaults to 3
#ldap_version 3
#
# Define if you want to use an encrypted LDAP connection.
# Typically, you must also set the port to 636 (ldaps).
#ssl on
#
# Define if you want to use port 389 and switch to
# encryption before the bind credentials are sent.
# Only supported by LDAP servers that support the start_tls
# extension such as OpenLDAP.
#ssl start_tls
#
# Additional TLS options follow that allow tweaking of the
# SSL/TLS connection.
#
#tls_checkpeer yes # verify server SSL certificate
#tls_checkpeer no # ignore server SSL certificate
#
# If you enable tls_checkpeer, specify either tls_cacertfile
# or tls_cacertdir. Only supported when using OpenLDAP.
#
#tls_cacertfile /etc/certs/trusted_signers.pem
#tls_cacertdir /etc/certs
#
# For systems that don't have /dev/random
# use this along with PRNGD or EGD.pl to seed the
# random number pool to generate cryptographic session keys.
```

```
# Only supported when using OpenLDAP.
#
#tls_randfile /etc/egd-pool
#
# You may restrict which ciphers are used. Consult your SSL
# documentation for which options go here.
# Only supported when using OpenLDAP.
#
#tls_ciphers <cipher-list>
#
# Sudo can provide a client certificate when communicating to
# the LDAP server.
# Tips:
# * Enable both lines at the same time.
# * Do not password protect the key file.
# * Ensure the keyfile is only readable by root.
#
# For OpenLDAP:
#tls_cert /etc/certs/client_cert.pem
#tls_key /etc/certs/client_key.pem
#
# For Netscape-derived LDAP, tls_cert and tls_key may specify either
# a directory, in which case the files in the directory must have the
# default names (e.g., cert8.db and key4.db), or the path to the cert
# and key files themselves. However, a bug in version 5.0 of the LDAP
# SDK will prevent specific file names from working. For this reason
# it is suggested that tls_cert and tls_key be set to a directory,
# not a file name.
#
# The certificate database specified by tls_cert may contain CA certs
# and/or the client's cert. If the client's cert is included, tls_key
# should be specified as well.
# For backward compatibility, "sslpath" may be used in place of tls_cert.
```

```
#tls_cert /var/ldap
#tls_key /var/ldap
#
# If using SASL authentication for LDAP (OpenSSL)
# use_sasl yes
# sasl_auth_id <SASL user name>
# rootuse_sasl yes
# rootsasl_auth_id <SASL user name for root access>
# sasl_secprops none
# krb5_ccname /etc/.ldapcache
```

#### Sudoers schema for OpenLDAP

The following schema, in OpenLDAP format, is included with sudo source and binary distributions as schema.OpenLDAP. Simply copy it to the schema directory (e.g., /etc/openldap/schema), add the proper include line in slapd.conf and restart slapd. Sites using the optional on-line configuration supported by OpenLDAP 2.3 and higher should apply the schema.olsudo file instead.

## AUTHORS

Many people have worked on sudo over the years; this version consists of code written primarily by:

Todd C. Miller

See the CONTRIBUTORS file in the sudo distribution

(<https://www.sudo.ws/contributors.html>) for an exhaustive list of people

who have contributed to sudo.

## CAVEATS

Note that there are differences in the way that LDAP-based sudoers is parsed compared to file-based sudoers. See the Differences between LDAP and non-LDAP sudoers section for more information.

## BUGS

If you feel you have found a bug in sudo, please submit a bug report at

<https://bugzilla.sudo.ws/>

## SUPPORT

Limited free support is available via the sudo-users mailing list, see

<https://www.sudo.ws/mailman/listinfo/sudo-users> to subscribe or search

the archives.

## DISCLAIMER

sudo is provided ?AS IS? and any express or implied warranties, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose are disclaimed. See the LICENSE file distributed with sudo or <https://www.sudo.ws/license.html> for complete details.
