$ man wordfree.3

WORDEXP(3) Linux Programmer's Manual WORDEXP(3)

NAME

wordexp, wordfree - perform word expansion like a posix-shell

SYNOPSIS

```
#include <wordexp.h>

int wordexp(const char *s, wordexp_t *p, int flags);

void wordfree(wordexp_t *p);
```

Feature Test Macro Requirements for glibc (see feature_test_macros(7)):

wordexp(), wordfree(): _XOPEN_SOURCE

DESCRIPTION

The function wordexp() performs a shell-like expansion of the string s and returns the result in the structure pointed to by p. The data type wordexp_t is a structure that at least has the fields we_wordc, we_wordv, and we_offs. The field we_wordc is a size_t that gives the number of words in the expansion of s. The field we_wordv is a char ** that points to the array of words found. The field we_offs of type size_t is sometimes (depending on flags, see below) used to indicate the number of initial elements in the we_wordv array that should be filled with NULLs.

The function wordfree() frees the allocated memory again. More pre? cisely, it does not free its argument, but it frees the array we_wordv and the strings that points to.

The string argument

Since the expansion is the same as the expansion by the shell (see sh(1)) of the parameters to a command, the string s must not contain characters that would be illegal in shell command parameters. In par? ticular, there must not be any unescaped newline or |, &, ;, <, >, (,), {, } characters outside a command substitution or parameter substi? tution context.

If the argument s contains a word that starts with an unquoted comment character #, then it is unspecified whether that word and all following words are ignored, or the # is treated as a non-comment character.

The expansion

The expansion done consists of the following stages: tilde expansion (replacing ~user by user's home directory), variable substitution (re? placing $FOO by the value of the environment variable FOO), command substitution (replacing $(command) or `command` by the output of com? mand), arithmetic expansion, field splitting, wildcard expansion, quote removal.

The result of expansion of special parameters ($@, $*, $#, $?, $-, $$, $!, $0) is unspecified.

Field splitting is done using the environment variable $IFS. If it is not set, the field separators are space, tab and newline.

The output array

The array we_wordv contains the words found, followed by a NULL.

The flags argument

The flag argument is a bitwise inclusive OR of the following values:

WRDE_APPEND

Append the words found to the array resulting from a previous call.

WRDE_DOOFFS

Insert we_offs initial NULLs in the array we_wordv. (These are not counted in the returned we_wordc.)

WRDE_NOCMD

Don't do command substitution.

WRDE_REUSE

The argument p resulted from a previous call to wordexp(), and wordfree() was not called. Reuse the allocated storage.

WRDE_SHOWERR

Normally during command substitution stderr is redirected to /dev/null. This flag specifies that stderr is not to be redi? rected.

WRDE_UNDEF

Consider it an error if an undefined shell variable is expanded.

RETURN VALUE

In case of success 0 is returned. In case of error one of the follow? ing five values is returned.

WRDE_BADCHAR

Illegal occurrence of newline or one of |, &, ;, <, >, (,), {, }.

WRDE_BADVAL

An undefined shell variable was referenced, and the WRDE_UNDEF flag told us to consider this an error.

WRDE_CMDSUB

Command substitution requested, but the WRDE_NOCMD flag told us to consider this an error.

WRDE_NOSPACE

Out of memory.

WRDE_SYNTAX

Shell syntax error, such as unbalanced parentheses or unmatched quotes.

VERSIONS

wordexp() and wordfree() are provided in glibc since version 2.1.

ATTRIBUTES

For an explanation of the terms used in this section, see at? tributes(7).

??

?Interface ? Attribute ? Value ?

??

?wordexp() ? Thread safety ? MT-Unsafe race:utent const:env ?

? ? ? env sig:ALRM timer locale ?

??

?wordfree() ? Thread safety ? MT-Safe ?

??

In the above table, utent in race:utent signifies that if any of the functions setutent(3), getutent(3), or endutent(3) are used in parallel in different threads of a program, then data races could occur. word? exp() calls those functions, so we use race:utent to remind users.

CONFORMING TO

POSIX.1-2001, POSIX.1-2008.

EXAMPLES

The output of the following example program is approximately that of "ls [a-c]*.c".

```
#include <stdio.h>
#include <stdlib.h>
#include <wordexp.h>
int
main(int argc, char **argv)
{
    wordexp_t p;
    char **w;
    wordexp("[a-c]*.c", &p, 0);
    w = p.we_wordv;
    for (int i = 0; i < p.we_wordc; i++)
        printf("%s\n", w[i]);
    wordfree(&p);
    exit(EXIT_SUCCESS);
}
```
