\$ man getopt_long_only.3

GETOPT(3) Linux Programmer's Manual GETOPT(3)

NAME

getopt, getopt_long, getopt_long_only, optarg, optind, opterr, optopt -
Parse command-line options

SYNOPSIS

```
#include <unistd.h>

int getopt(int argc, char * const argv[],
           const char *optstring);

extern char *optarg;
extern int optind, opterr, optopt;

#include <getopt.h>

int getopt_long(int argc, char * const argv[],
               const char *optstring,
               const struct option *longopts, int *longindex);

int getopt_long_only(int argc, char * const argv[],
                    const char *optstring,
                    const struct option *longopts, int *longindex);
```

getopt(): `_POSIX_C_SOURCE >= 2 || _XOPEN_SOURCE`

getopt_long(), getopt_long_only(): `_GNU_SOURCE`

DESCRIPTION

The `getopt()` function parses the command-line arguments. Its arguments `argc` and `argv` are the argument count and array as passed to the `main()` function on program invocation. An element of `argv` that starts with `'-'` (and is not exactly `"-"` or `"--"`) is an option element. The characters of this element (aside from the initial `'-'`) are option characters. If `getopt()` is called repeatedly, it returns successively each of the option characters from each of the option elements.

The variable `optind` is the index of the next element to be processed in `argv`. The system initializes this value to 1. The caller can reset it to 1 to restart scanning of the same `argv`, or when scanning a new argument vector.

If `getopt()` finds another option character, it returns that character, updating the external variable `optind` and a static variable `nextchar` so that the next call to `getopt()` can resume the scan with the following option character or `argv`-element.

If there are no more option characters, `getopt()` returns `-1`. Then `optind` is the index in `argv` of the first `argv`-element that is not an option.

`optstring` is a string containing the legitimate option characters. If such a character is followed by a colon, the option requires an argument, so `getopt()` places a pointer to the following text in the same `argv`-element, or the text of the following `argv`-element, in `optarg`.

Two colons mean an option takes an optional arg; if there is text in the current `argv`-element (i.e., in the same word as the option name itself, for example, `"-oarg"`), then it is returned in `optarg`, otherwise `optarg` is set to zero. This is a GNU extension. If `optstring` contains `W` followed by a semicolon, then `-W foo` is treated as the long option `--foo`. (The `-W` option is reserved by POSIX.2 for implementation extensions.) This behavior is a GNU extension, not available with libraries before glibc 2.

By default, `getopt()` permutes the contents of `argv` as it scans, so that eventually all the nonoptions are at the end. Two other scanning modes are also implemented. If the first character of `optstring` is '+' or the environment variable `POSIXLY_CORRECT` is set, then option processing stops as soon as a nonoption argument is encountered. If the first character of `optstring` is '-', then each nonoption `argv`-element is handled as if it were the argument of an option with character code 1. (This is used by programs that were written to expect options and other `argv`-elements in any order and that care about the ordering of the two.) The special argument "--" forces an end of option-scanning regardless of the scanning mode.

While processing the option list, `getopt()` can detect two kinds of errors: (1) an option character that was not specified in `optstring` and (2) a missing option argument (i.e., an option at the end of the command line without an expected argument). Such errors are handled and reported as follows:

- * By default, `getopt()` prints an error message on standard error, places the erroneous option character in `optopt`, and returns '?' as the function result.
- * If the caller has set the global variable `opterr` to zero, then `getopt()` does not print an error message. The caller can determine that there was an error by testing whether the function return value is '?'. (By default, `opterr` has a nonzero value.)
- * If the first character (following any optional '+' or '-' described above) of `optstring` is a colon (':'), then `getopt()` likewise does not print an error message. In addition, it returns ':' instead of '?' to indicate a missing option argument. This allows the caller to distinguish the two different types of errors.

`getopt_long()` and `getopt_long_only()`

The `getopt_long()` function works like `getopt()` except that it also accepts long options, started with two dashes. (If the program accepts only long options, then `optstring` should be specified as an empty string (""), not `NULL`.) Long option names may be abbreviated if the

abbreviation is unique or is an exact match for some defined option. A long option may take a parameter, of the form `--arg=param` or `--arg param`.

`longopts` is a pointer to the first element of an array of struct option declared in `<getopt.h>` as

```
struct option {
    const char *name;
    int      has_arg;
    int      *flag;
    int      val;
};
```

The meanings of the different fields are:

`name` is the name of the long option.

`has_arg`

is: `no_argument` (or 0) if the option does not take an argument; `required_argument` (or 1) if the option requires an argument; or `optional_argument` (or 2) if the option takes an optional argument.

`flag` specifies how results are returned for a long option. If `flag` is `NULL`, then `getopt_long()` returns `val`. (For example, the calling program may set `val` to the equivalent short option character.) Otherwise, `getopt_long()` returns 0, and `flag` points to a variable which is set to `val` if the option is found, but left unchanged if the option is not found.

`val` is the value to return, or to load into the variable pointed to by `flag`.

The last element of the array has to be filled with zeros.

If `longindex` is not `NULL`, it points to a variable which is set to the index of the long option relative to `longopts`.

`getopt_long_only()` is like `getopt_long()`, but '-' as well as "--" can indicate a long option. If an option that starts with '-' (not "--") doesn't match a long option, but does match a short option, it is parsed as a short option instead.

RETURN VALUE

If an option was successfully found, then `getopt()` returns the option character. If all command-line options have been parsed, then `getopt()` returns -1. If `getopt()` encounters an option character that was not in `optstring`, then '?' is returned. If `getopt()` encounters an option with a missing argument, then the return value depends on the first character in `optstring`: if it is ':', then ':' is returned; otherwise '?' is returned.

`getopt_long()` and `getopt_long_only()` also return the option character when a short option is recognized. For a long option, they return the value of `flag` if `flag` is NULL, and 0 otherwise. Error and -1 returns are the same as for `getopt()`, plus '?' for an ambiguous match or an extraneous parameter.

ENVIRONMENT

POSIXLY_CORRECT

If this is set, then option processing stops as soon as a nonoption argument is encountered.

`_<PID>_GNU_nonoption_argv_flags_`

This variable was used by `bash(1)` 2.0 to communicate to `glibc` which arguments are the results of wildcard expansion and so should not be considered as options. This behavior was removed in `bash(1)` version 2.01, but the support remains in `glibc`.

ATTRIBUTES

For an explanation of the terms used in this section, see `attributes(7)`.

??

?Interface ? Attribute ? Value ?

??

?`getopt()`, `getopt_long()`, ? Thread safety ? MT-Unsafe race:`getopt` env ?

?`getopt_long_only()` ? ? ?

??

CONFORMING TO

`getopt()`:

POSIX.1-2001, POSIX.1-2008, and POSIX.2, provided the environment variable POSIXLY_CORRECT is set. Otherwise, the elements of argv aren't really const, because these functions permute them. Nevertheless, const is used in the prototype to be compatible with other systems.

The use of '+' and '-' in optstring is a GNU extension.

On some older implementations, getopt() was declared in <stdio.h>. SUSv1 permitted the declaration to appear in either <unistd.h> or <stdio.h>. POSIX.1-1996 marked the use of <stdio.h> for this purpose as LEGACY. POSIX.1-2001 does not require the declaration to appear in <stdio.h>.

getopt_long() and getopt_long_only():

These functions are GNU extensions.

NOTES

A program that scans multiple argument vectors, or rescans the same vector more than once, and wants to make use of GNU extensions such as '+' and '-' at the start of optstring, or changes the value of POSIXLY_CORRECT between scans, must reinitialize getopt() by resetting optind to 0, rather than the traditional value of 1. (Resetting to 0 forces the invocation of an internal initialization routine that rechecks POSIXLY_CORRECT and checks for GNU extensions in optstring.)

EXAMPLES

getopt()

The following trivial example program uses getopt() to handle two program options: -n, with no associated value; and -t val, which expects an associated value.

```
#include <unistd.h>
```

```
#include <stdlib.h>
```

```
#include <stdio.h>
```

```
int
```

```
main(int argc, char *argv[])
```

```
{
```

```
    int flags, opt;
```

```

int nsecs, tfnd;

nsecs = 0;

tfnd = 0;

flags = 0;

while ((opt = getopt(argc, argv, "nt:")) != -1) {
    switch (opt) {
        case 'n':
            flags = 1;

            break;

        case 't':
            nsecs = atoi(optarg);

            tfnd = 1;

            break;

        default: /* '?' */

            fprintf(stderr, "Usage: %s [-t nsecs] [-n] name\n",
                argv[0]);

            exit(EXIT_FAILURE);

    }
}

printf("flags=%d; tfnd=%d; nsecs=%d; optind=%d\n",
    flags, tfnd, nsecs, optind);

if (optind >= argc) {
    fprintf(stderr, "Expected argument after options\n");

    exit(EXIT_FAILURE);
}

printf("name argument = %s\n", argv[optind]);

/* Other code omitted */

exit(EXIT_SUCCESS);
}

getopt_long()

```

The following example program illustrates the use of `getopt_long()` with most of its features.

```
#include <stdio.h> /* for printf */
```

```

#include <stdlib.h> /* for exit */
#include <getopt.h>

int
main(int argc, char **argv)
{
    int c;
    int digit_optind = 0;
    while (1) {
        int this_option_optind = optind ? optind : 1;
        int option_index = 0;
        static struct option long_options[] = {
            {"add",    required_argument, 0, 0 },
            {"append", no_argument,      0, 0 },
            {"delete", required_argument, 0, 0 },
            {"verbose", no_argument,      0, 0 },
            {"create", required_argument, 0, 'c'},
            {"file",   required_argument, 0, 0 },
            {0,       0,                  0, 0 }
        };
        c = getopt_long(argc, argv, "abc:d:012",
            long_options, &option_index);
        if (c == -1)
            break;
        switch (c) {
        case 0:
            printf("option %s", long_options[option_index].name);
            if (optarg)
                printf(" with arg %s", optarg);
            printf("\n");
            break;
        case '0':
        case '1':
        case '2':

```

```

    if (digit_optind != 0 && digit_optind != this_option_optind)
        printf("digits occur in two different argv-elements.\n");
    digit_optind = this_option_optind;
    printf("option %c\n", c);
    break;
case 'a':
    printf("option a\n");
    break;
case 'b':
    printf("option b\n");
    break;
case 'c':
    printf("option c with value '%s'\n", optarg);
    break;
case 'd':
    printf("option d with value '%s'\n", optarg);
    break;
case '?':
    break;
default:
    printf("?? getopt returned character code 0%o ??\n", c);
}
}
if (optind < argc) {
    printf("non-option ARGV-elements: ");
    while (optind < argc)
        printf("%s ", argv[optind++]);
    printf("\n");
}
exit(EXIT_SUCCESS);
}

```
