INET\_NET\_PTON(3)

Linux Programmer's Manual

INET\_NET\_PTON(3)

NAME

inet net pton, inet net ntop - Internet network number conversion

# **SYNOPSIS**

```
#include <arpa/inet.h>
```

int inet\_net\_pton(int af, const char \*pres,

void \*netp, size\_t nsize);

char \*inet\_net\_ntop(int af, const void \*netp, int bits,

char \*pres, size\_t psize);

Link with -lresolv.

Feature Test Macro Requirements for glibc (see feature\_test\_macros(7)):

inet\_net\_pton(), inet\_net\_ntop():

Since glibc 2.20:

\_DEFAULT\_SOURCE

Before glibc 2.20:

\_BSD\_SOURCE || \_SVID\_SOURCE

## **DESCRIPTION**

printable) format and network (i.e., binary) format.

For both functions, af specifies the address family for the conversion; the only supported value is AF\_INET.

### inet\_net\_pton()

The inet\_net\_pton() function converts pres, a null-terminated string containing an Internet network number in presentation format to network format. The result of the conversion, which is in network byte order, is placed in the buffer pointed to by net. (The netp argument typi? cally points to an in\_addr structure.) The nsize argument specifies the number of bytes available in netp.

On success, inet\_net\_pton() returns the number of bits in the network number field of the result placed in netp. For a discussion of the in? put presentation format and the return value, see NOTES.

Note: the buffer pointed to by netp should be zeroed out before calling inet\_net\_pton(), since the call writes only as many bytes as are re? quired for the network number (or as are explicitly specified by pres), which may be less than the number of bytes in a complete network ad? dress.

## inet\_net\_ntop()

The inet\_net\_ntop() function converts the network number in the buffer pointed to by netp to presentation format; \*netp is interpreted as a value in network byte order. The bits argument specifies the number of bits in the network number in \*netp.

The null-terminated presentation-format string is placed in the buffer pointed to by pres. The psize argument specifies the number of bytes available in pres. The presentation string is in CIDR format: a dot? ted-decimal number representing the network address, followed by a slash, and the size of the network number in bits.

## **RETURN VALUE**

On success, inet\_net\_pton() returns the number of bits in the network number. On error, it returns -1, and errno is set to indicate the cause of the error.

On success, inet\_net\_ntop() returns pres. On error, it returns NULL,

and errno is set to indicate the cause of the error.

## **ERRORS**

#### **EAFNOSUPPORT**

af specified a value other than AF\_INET.

#### **EMSGSIZE**

The size of the output buffer was insufficient.

ENOENT (inet\_net\_pton()) pres was not in correct presentation format.

## **CONFORMING TO**

The inet\_net\_pton() and inet\_net\_ntop() functions are nonstandard, but widely available.

#### **NOTES**

Input presentation format for inet\_net\_pton()

The network number may be specified either as a hexadecimal value or in dotted-decimal notation.

Hexadecimal values are indicated by an initial "0x" or "0X". The hexa? decimal digits populate the nibbles (half octets) of the network number from left to right in network byte order.

In dotted-decimal notation, up to four octets are specified, as decimal numbers separated by dots. Thus, any of the following forms are ac? cepted:

a.b.c.d

a.b.c

a.b

а

Each part is a number in the range 0 to 255 that populates one byte of the resulting network number, going from left to right, in network-byte (big endian) order. Where a part is omitted, the resulting byte in the network number is zero.

For either hexadecimal or dotted-decimal format, the network number can optionally be followed by a slash and a number in the range 0 to 32, which specifies the size of the network number in bits.

Return value of inet\_net\_pton()

The return value of inet\_net\_pton() is the number of bits in the net?

work number field. If the input presentation string terminates with a slash and an explicit size value, then that size becomes the return value of inet\_net\_pton(). Otherwise, the return value, bits, is in? ferred as follows:

- \* If the most significant byte of the network number is greater than or equal to 240, then bits is 32.
- \* Otherwise, if the most significant byte of the network number is greater than or equal to 224, then bits is 4.
- \* Otherwise, if the most significant byte of the network number is greater than or equal to 192, then bits is 24.
- \* Otherwise, if the most significant byte of the network number is greater than or equal to 128, then bits is 16.
- \* Otherwise, bits is 8.

If the resulting bits value from the above steps is greater than or equal to 8, but the number of octets specified in the network number exceed bits/8, then bits is set to 8 times the number of octets actu? ally specified.

## **EXAMPLES**

The program below demonstrates the use of inet\_net\_pton() and inet\_net\_ntop(). It uses inet\_net\_pton() to convert the presentation format network address provided in its first command-line argument to binary form, displays the return value from inet\_net\_pton(). It then uses inet\_net\_ntop() to convert the binary form back to presentation format, and displays the resulting string.

In order to demonstrate that inet\_net\_pton() may not write to all bytes of its netp argument, the program allows an optional second command-line argument, a number used to initialize the buffer before inet\_net\_pton() is called. As its final line of output, the program displays all of the bytes of the buffer returned by inet\_net\_pton() al? lowing the user to see which bytes have not been touched by inet\_net\_pton().

An example run, showing that inet\_net\_pton() infers the number of bits in the network number:

```
$./a.out 193.168
    inet_net_pton() returned: 24
    inet_net_ntop() yielded: 193.168.0/24
                           c1a80000
    Raw address:
  Demonstrate that inet_net_pton() does not zero out unused bytes in its
  result buffer:
    $ ./a.out 193.168 0xffffffff
    inet_net_pton() returned: 24
    inet net ntop() yielded: 193.168.0/24
    Raw address:
                           c1a800ff
  Demonstrate that inet_net_pton() will widen the inferred size of the
  network number, if the supplied number of bytes in the presentation
  string exceeds the inferred value:
    $ ./a.out 193.168.1.128
    inet_net_pton() returned: 32
    inet_net_ntop() yielded: 193.168.1.128/32
    Raw address:
                           c1a80180
  Explicitly specifying the size of the network number overrides any in?
  ference about its size (but any extra bytes that are explicitly speci?
  fied will still be used by inet_net_pton(): to populate the result buf?
  fer):
    $ ./a.out 193.168.1.128/24
    inet_net_pton() returned: 24
    inet_net_ntop() yielded: 193.168.1/24
    Raw address:
                           c1a80180

```
main(int argc, char *argv[])
  char buf[100];
  struct in_addr addr;
  int bits;
  if (argc < 2) {
     fprintf(stderr,
          "Usage: %s presentation-form [addr-init-value]\n",
          argv[0]);
     exit(EXIT_FAILURE);
  }
  /* If argv[2] is supplied (a numeric value), use it to initialize
    the output buffer given to inet_net_pton(), so that we can see
    that inet_net_pton() initializes only those bytes needed for
    the network number. If argv[2] is not supplied, then initialize
    the buffer to zero (as is recommended practice). */
  addr.s\_addr = (argc > 2) ? strtod(argv[2], NULL) : 0;
  /* Convert presentation network number in argv[1] to binary */
  bits = inet_net_pton(AF_INET, argv[1], &addr, sizeof(addr));
  if (bits == -1)
     errExit("inet_net_ntop");
  printf("inet_net_pton() returned: %d\n", bits);
  /* Convert binary format back to presentation, using 'bits'
    returned by inet_net_pton() */
  if (inet_net_ntop(AF_INET, &addr, bits, buf, sizeof(buf)) == NULL)
     errExit("inet_net_ntop");
  printf("inet_net_ntop() yielded: %s\n", buf);
  /* Display 'addr' in raw form (in network byte order), so we can
    see bytes not displayed by inet_net_ntop(); some of those bytes
    may not have been touched by inet_net_ntop(), and so will still
    have any initial value that was specified in argv[2]. */
  printf("Raw address:
                                %x\n", htonl(addr.s_addr));
  exit(EXIT_SUCCESS);
```

```
}
