SG_STPG(8)   SG3_UTILS   SG_STPG(8)

NAME

    sg_stpg - send SCSI SET TARGET PORT GROUPS command

SYNOPSIS

    sg_stpg [--active] [--help] [--hex] [--offline] [--optimized] [--raw]

    [--standby] [--state=S,S...] [--tp=P,P...] [--unavailable] [--verbose]

    [--version] DEVICE

DESCRIPTION

    Send a SCSI SET TARGET PORT GROUPS command to DEVICE. This utility has

    different modes depending on whether the --tp= option is given.

    If --tp= is given then the SET TARGET PORT GROUPS command parameter

    block is built with a descriptor for each element in the list given to

    --tp=. The corresponding asymmetric access state value is either taken

    from the --state= list or, if that is not given, from one of the ex?

    plicit state options (e.g. --unavailable), used repeatedly if required.

    If --tp= is not given then a sequence of SCSI commands are sent to the

    DEVICE leading up to the SET TARGET PORT GROUPS command. First an IN?

    QUIRY is sent to fetch the device identification VPD page to find the

(primary) target port group associated with DEVICE. Then a REPORT TAR?

GET PORT GROUPS command is issued to find the current state and whether

a transition to the requested state is supported. If so the SET TARGET

PORT GROUPS command is sent.

Target port group access is described in SPC-4 found at www.t10.org in

sections 5.8 and 5.16 (in rev 36e dated 2012/8/24). The SET TARGET PORT

GROUPS command is also described in section 6.45 of that document.

OPTIONS

Arguments to long options are mandatory for short options as well. The

options are arranged in alphabetical order based on the long option

name.

-a, --active

set active/non-optimized state.

-h, --help

output the usage message then exit.

-H, --hex

output response to the REPORT TARGET PORT GROUPS command in hex

then exit.

-O, -l, --offline

set offline state. This is the appropriate state to set a target

port to prior to removing the device. Note that a relative tar?

get port identifier should be given with this state (rather than

a target port group identifier that all other states take).

-o, --optimized

set active/optimized state. If no other state options or --tp=

option are given then active/optimized is the default state.

-r, --raw

output response to the REPORT TARGET PORT GROUPS command in bi?

nary to stdout then exit.

-s, --standby

set standby state. Port group shall accept those commands listed

for "unavailable" state plus LOG SELECT/SENSE, MODE SE?

LECT/SENSE, RECEIVE DIAGNOSTIC RESULTS, SEND DIAGNOSTIC, PERSIS?

TENT RESERVE IN/OUT commands.

-S, --state=S,S...

  specifies a comma separated list (one element of more) of
  states. Either a number or an abbreviation can be given. A num?
  ber is assumed to be a decimal number unless it is prefixed by
  "0x" or has a trailing "h" in which case a hexadecimal value is
  assumed. Only the values 0, 1, 2, 3 or 14 are accepted. The ac?
  cepted abbreviations are "an", "ao", "o", "s" or "u"; which rep?
  resent active/non-optimized(1), active/optimized(0), off?
  line(14), standby(2) or unavailable(3) respectively.

-t, --tp=P,P...

  specifies a comma separated list (one element of more). Each el?
  ements is either a target port group identifier (when the corre?
  sponding state is other than "offline") or a relative target
  port identifier (when the corresponding state is "offline").
  Each element is assumed to be a decimal number unless it is pre?
  fixed by "0x" or has a trailing "h" in which case a hexadecimal
  value is assumed.

-u, --unavailable

  set unavailable state. Port group shall only accept INQUIRY, RE?
  PORT LUNS, REPORT/SET TARGET PORT GROUPS, REQUEST SENSE and
  READ/WRITE BUFFER commands.

-v, --verbose

  increase the level of verbosity, (i.e. debug output).

-V, --version

  print the version string and then exit.

NOTES

The SET TARGET PORT GROUPS command should be supported whenever the
TPGS value in a standard INQUIRY response is 2 or 3. [View with sg_inq
utility.]

Notice that the offline state is termed as a "secondary target port
asymmetric access state" and takes a relative target port identifier
(i.e. acts on a single target port). All the other states are termed

as "primary target port asymmetric access states" and each takes a tar?

get port group identifier (i.e. acts on one or more target ports).

When --tp= is given then the same number of elements should be given to

the --state= option. If more than one list element is given to --tp=

and an equal number of elements is _not_ given to the --state= option,

then if only one state is specified then it is repeated.

EXIT STATUS

The exit status of sg_stpg is 0 when it is successful. Otherwise see

the sg3_utils(8) man page.
