SHM\_OVERVIEW(7)

Linux Programmer's Manual

SHM\_OVERVIEW(7)

## NAME

shm\_overview - overview of POSIX shared memory

## DESCRIPTION

The POSIX shared memory API allows processes to communicate information

by sharing a region of memory.

The interfaces employed in the API are:

shm\_open(3) Create and open a new object, or open an existing ob?

ject. This is analogous to open(2). The call returns a

file descriptor for use by the other interfaces listed

below.

- ftruncate(2) Set the size of the shared memory object. (A newly cre? ated shared memory object has a length of zero.)
- mmap(2) Map the shared memory object into the virtual address space of the calling process.
- munmap(2) Unmap the shared memory object from the virtual address space of the calling process.
- shm\_unlink(3) Remove a shared memory object name.

- close(2) Close the file descriptor allocated by shm\_open(3) when it is no longer needed.
- fstat(2) Obtain a stat structure that describes the shared memory object. Among the information returned by this call are the object's size (st\_size), permissions (st\_mode), owner (st\_uid), and group (st\_gid).

fchown(2) To change the ownership of a shared memory object.

fchmod(2) To change the permissions of a shared memory object.

#### Versions

POSIX shared memory is supported since Linux 2.4 and glibc 2.2.

Persistence

POSIX shared memory objects have kernel persistence: a shared memory object will exist until the system is shut down, or until all processes

have unmapped the object and it has been deleted with shm\_unlink(3)

#### Linking

Programs using the POSIX shared memory API must be compiled with cc

-Irt to link against the real-time library, librt.

Accessing shared memory objects via the filesystem

On Linux, shared memory objects are created in a (tmpfs(5)) virtual filesystem, normally mounted under /dev/shm. Since kernel 2.6.19, Linux supports the use of access control lists (ACLs) to control the permissions of objects in the virtual filesystem.

#### NOTES

Typically, processes must synchronize their access to a shared memory object, using, for example, POSIX semaphores.

System V shared memory (shmget(2), shmop(2), etc.) is an older shared memory API. POSIX shared memory provides a simpler, and better de? signed interface; on the other hand POSIX shared memory is somewhat less widely available (especially on older systems) than System V shared memory.
