SYSTEMD-PSTORE.SERVICE(8) systemd-pstore.service SYSTEMD-PSTORE.SERVICE(8)

# NAME

systemd-pstore.service, systemd-pstore - A service to archive contents

of pstore

# SYNOPSIS

/usr/lib/systemd/systemd-pstore

systemd-pstore.service

# DESCRIPTION

systemd-pstore.service is a system service that archives the contents

of the Linux persistent storage filesystem, pstore, to other storage,

thus preserving the existing information contained in the pstore, and

clearing pstore storage for future error events.

Linux provides a persistent storage file system, pstore, that can store

error records when the kernel dies (or reboots or powers-off). These

records in turn can be referenced to debug kernel problems (currently

the kernel stores the tail of the kernel log, which also contains a

stack backtrace, into pstore).

The pstore file system supports a variety of backends that map onto

persistent storage, such as the ACPI ERST and UEFI variables. The pstore backends typically offer a relatively small amount of persistent storage, e.g. 64KiB, which can quickly fill up and thus prevent subsequent kernel crashes from recording errors. Thus there is a need to monitor and extract the pstore contents so that future kernel problems can also record information in the pstore.

The pstore service is independent of the kdump service. In cloud environments specifically, host and guest filesystems are on remote filesystems (e.g. iSCSI or NFS), thus kdump relies (implicitly and/or explicitly) upon proper operation of networking software \*and\* hardware \*and\* infrastructure. Thus it may not be possible to capture a kernel coredump to a file since writes over the network may not be possible. The pstore backend, on the other hand, is completely local and provides a path to store error records which will survive a reboot and aid in post-mortem debugging.

The systemd-pstore executable does the actual work. Upon starting, the pstore.conf file is read and the /sys/fs/pstore/ directory contents are processed according to the options. Pstore files are written to the journal, and optionally saved into /var/lib/systemd/pstore/.

#### CONFIGURATION

The behavior of systemd-pstore is configured through the configuration file /etc/systemd/pstore.conf and corresponding snippets /etc/systemd/pstore.conf.d/\*.conf, see pstore.conf(5).

#### Disabling pstore processing

To disable pstore processing by systemd-pstore, set

Storage=none

in pstore.conf(5).

#### Kernel parameters

The kernel has two parameters,

/sys/module/kernel/parameters/crash\_kexec\_post\_notifiers and

/sys/module/printk/parameters/always\_kmsg\_dump, that control writes

into pstore. The first enables storing of the kernel log (including

stack trace) into pstore upon a panic or crash, and the second enables

storing of the kernel log upon a normal shutdown (shutdown, reboot,

halt). These parameters can be managed via the tmpfiles.d(5) mechanism,

specifically the file /usr/lib/tmpfiles/systemd-pstore.conf.

# USAGE

Data stored in the journal can be viewed with journalctl(1) as usual.
