NAME
lxterm − locale−sensitive wrapper for xterm

SYNOPSIS
lxterm [*xterm-options*]

DESCRIPTION
lxterm is a wrapper around the **xterm**(1) program that invokes **xterm**, **koi8rxterm**(1), or **uxterm**(1) as appropriate, based on the user's locale setting. All arguments to **lxterm** are passed to **xterm** without processing; the **−class**, **−k8**, and **−u8** options should not be specified because they are used by **koi8rxterm** and **uxterm**. See the **xterm** manual page for more information on *xterm-options*.

The **locale**(1) utility is used to determine the character set used by the current locale. If the character set is UTF-8, **uxterm** is invoked; if the character set is KOI8-R, **koi8rxtem** is invoked; otherwise, 'plain' **xterm** is invoked.
