

NAME

projid – the project name mapping file

DESCRIPTION

The */etc/projid* file provides a mapping between numeric project identifiers and a simple human readable name (similar relationship to the one that exists between usernames and uids). Its format is simply:

```
# comments are hash-prefixed
# ...
cage:10
logfiles:42
```

This file is optional, if a project identifier cannot be mapped to a name, it will be parsed and displayed as a numeric value.
